Section 1

Introduction

This amendment to the Zone 40 Water Supply Master Plan (WSMP) has been prepared for the proposed Multi-Sport Complex (MSC) and Grant Line Industrial Annexation Area. The MSC is part of the Grant Line Industrial Annexation Area is known as the Plan Area (Plan Area). This amendment is developed at the request of the City of Elk Grove Planning Department (Local Agency Formation Commission (LAFCo) # 04-15). This section describes Sacramento County Water Agency (SCWA) and Zone 40, the purpose of this amendment, linkage to the 2005 WSMP (SCWA, 2005), the Zone 40 service area, and the report organization.

1.1 SCWA and Zone 40

SCWA was formed in 1952 by a special legislative act of the State of California called the Sacramento County Water Agency Act (Agency Act). SCWA is governed by a Board of Directors. Under the Agency Act, the Board may contract with the federal government and the State of California with respect to the purchase, sale, and acquisition of water. SCWA may also construct and operate any required capital facilities.

Zone 40 was created by among other things SCWA Resolution No. 663 in May 1985, which described the boundaries of the zone and the types of projects to be undertaken. Zone 40 is a benefit zone created for the acquisition, construction, maintenance, and operation of facilities for the production, conservation, transmittal, distribution, and sale of ground or surface water or both for the present and future beneficial use of lands or inhabitants within the zone. Ordinance No. 18, adopted in 1986, empowered SCWA to establish fees, charges, credits, and regulations for the supply of water and required the development of a water supply master plan. The boundaries and scope of Zone 40's activities were expanded in April 1999 by Resolution WA-2331 to include the use of recycled water in conjunction with surface and groundwater. The Zone 40 boundary was further amended for Cordova Hills in 2011 as described in the SCWA Board of Directors Resolution WA-2844 dated March 26, 2013.

SCWA provides retail water supply within Zone 40 to portions of unincorporated Sacramento County, the City of Rancho Cordova, and the City of Elk Grove. SCWA also provides wholesale water supply to a portion of the service area of Elk Grove Water District. Elk Grove Water District operates a retail water system serving customers within a portion of the City of Elk Grove and is a department of the Florin Resource Conservation District. SCWA will also provide wholesale water supply in the future to California American Water Company's (Cal Am) service area in Rio del Oro.

1.2 Purpose

The purpose of this WSMP Amendment is to address the sufficiency of water supply for the 2030 study area that is updated to include the Plan Area, which includes the proposed MSC, and to update relevant assumptions contained within the WSMP (February 2005). Significant changes such as water supply variations, County General Plan Amendments, annexations, incorporations, or new major programs are treated through formal updates or amendments to the WSMP.

The 2005 WSMP was developed to provide a flexible program of water management alternatives that could be implemented as the availability and feasibility of water supply sources change. It

presented recommendations to meet future water demands in Zone 40 through the year 2030 (identified as the 2030 Study Area) with a regional conjunctive use program balancing the use of groundwater, surface water, and recycled water supplies. The Freeport Regional Water Project alternative was selected as the preferred alternative.

- Subsequently, SCWA developed the following documents:
- 2006 Zone 40 Water System Infrastructure Plan (WSIP) (SCWA, September 2006)
- 2006 Central Sacramento County Groundwater Management Plan
- 2010 Urban Water Management Plan (UWMP) (SCWA, July 2011)
- 2011 Water Supply Master Plan Amendment for the Cordova Hills Project (SCWA, December 2011)
- Draft WSMP Amendments for Jackson Township, NewBridge, and West Jackson Projects created at the request of the Sacramento County Office of Planning and Environmental Review (SCWA, three reports, February 2016)
- 2015 UWMP (SCWA, June 2016)
- 2016 Zone 40 WSIP (SCWA, September 2016)

Since the completion of these documents, the Plan Area has been proposed. The completion of this WSMP amendment is a necessary component for the approval of the proposed Plan Area as required by LAFCo# 04-15. The proposed Plan Area is located just outside of the City of Elk Grove's southern city limit, east of Highway 99 and the railroad and south of Grant Line Road. Because the Plan Area is located outside of the 2005 WSMP study area, SCWA is required to develop and approve an amendment to the WSMP to serve the area with potable water.

This WSMP amendment presents an evaluation of the water demands, water supplies, water system facilities, and costs for two scenarios, as follows:

- Baseline. This scenario consists of Zone 40 with the land uses as currently approved plus three other previously planned projects known as West Jackson, Jackson Township, and NewBridge.
- Plan Area. This scenario consists of the Baseline scenario plus the proposed Plan Area, which is described in Section 8.

1.3 Linkage to 2005 Zone 40 Water Supply Master Plan

This WSMP Amendment contains updates and additions to substantial portions of the 2005 WSMP and the 2011 Cordova Hills Amendment. The items that have been updated include buildout land use acreages, unit water demand factors, recent historical demographics and water demands, projected water demands, growth rate projection, projected water supply availability, groundwater supply description, needed future facilities, and the capital improvement plan (CIP). New items that are presented in this Amendment that were not included in the 2005 WSMP and the 2011 Cordova Hills include existing water facilities descriptions; buildout population, connections, and dwelling units by service area; water demand factors expressed as demand per dwelling unit and per type of customer; projected maximum day and annual use of surface water and groundwater for dry and wet/average years; evaluation of storage and pump station capacity; and cost estimates for each proposed facility.

1.4 Service Area Description

The Zone 40 boundary and service areas as well as the Plan Area are shown on Figure 1-1. The study area for this analysis is the same as for the WSMP and the Cordova Hills Master Plan Amendment

and only revised to include the Plan Area. The study area is further described and illustrated in Section 3.

The Zone 40 has three service areas as follows:

- North Service Area (NSA)
- Central Service Area (CSA)
- South Service Area (SSA)

1.4.1 North Service Area

The NSA is located south of the American River and includes part of the City of Rancho Cordova. Historically, the NSA was supplied exclusively by groundwater. In recent years, SCWA has supplied surface water supply to the NSA, from the Vineyard WTP, as part of the conjunctive use program. The NSA is the least developed of the three service areas, with currently less than 10 percent of the projected build out population. This service area includes the old Mather and Sunrise Corridor systems, as well as the newer Sunridge system. SCWA assumed ownership of the Mather System shortly after the County of Sacramento took over the old Mather Air Force Base after it was shut down by the US Air Force in the mid-1990s. In the case of the Sunrise Corridor System, SCWA was asked to take ownership and provide water service after the system was constructed through an assessment district in the late 1980's. The majority of the land within the NSA boundary is rural and undeveloped.

1.4.2 Central Service Area

The CSA is located to the south of the NSA and is supplied by surface water from the Vineyard Surface Water Treatment Plant (SWTP) and groundwater. The Plan Area will be part of the CSA. The CSA is partially developed with approximately 27 percent of the projected build out population. SCWA provides wholesale water to Elk Grove Water District within the CSA. This service area includes the old Grantline-99 system, as well as the newer Vineyard, Vineyard Springs, and North Vineyard Station areas. The CSA is predominately residential with a small amount of commercial and institutional customers and a large rural component to the east. The Plan Area is located adjacent to the existing CSA.

1.4.3 South Service Area

The SSA is located south of the CSA and to the west of Highway 99. The SSA is the most developed of the three service areas, with currently 60 percent of the projected build out population. The SSA is supplied by a mix of surface water, groundwater, and recycled water. The surface water comes from the Vineyard SWTP and conveyed through the CSA. The Franklin Intertie can also supply surface water but has not been operated in recent years. This service area currently supplies the Laguna, East Franklin, and Laguna Ridge areas. The SSA is predominantly residential with some commercial and institutional customers as well.

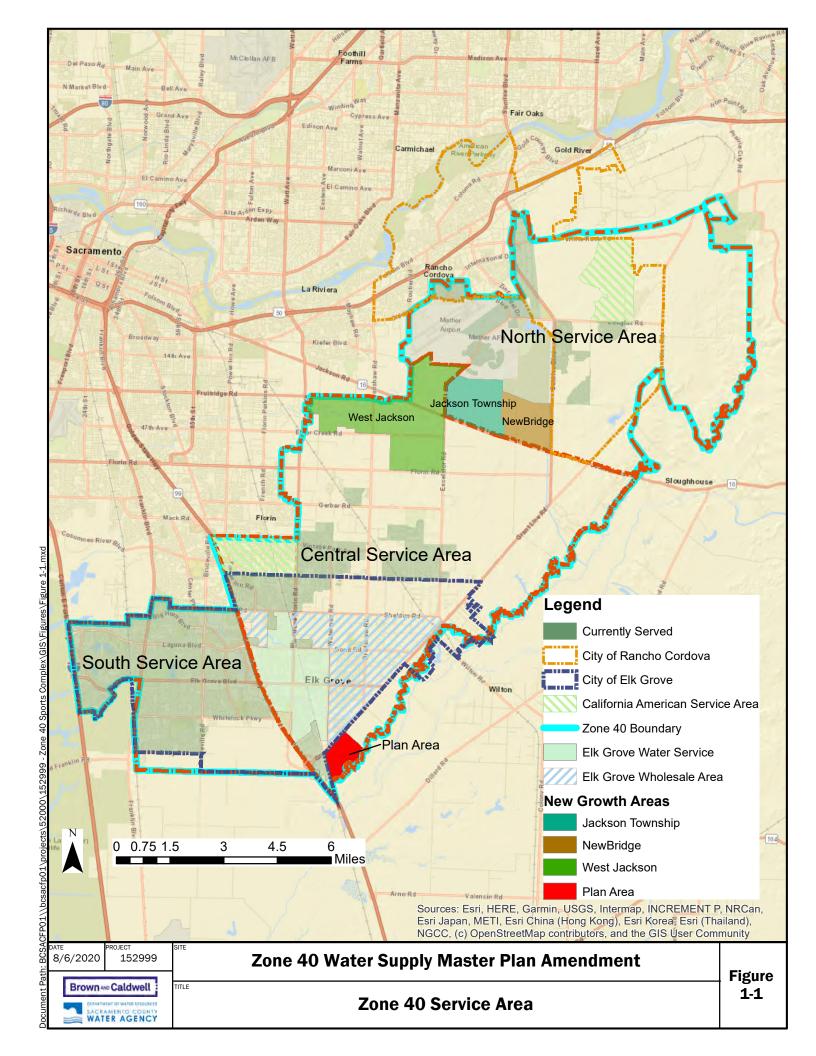

1.5 Report Organization

The WSMP contains the following nine sections plus appendices, as follows:

- Section 2 presents a description of the existing water system and its facilities.
- Section 3 presents the methodology used to develop future water demands, the connection growth projection, and the water demand factors.
- Section 4 describes the water supplies.
- Section 5 describes the approach to quantify the amount of needed supply and storage capacity.
- Section 6 describes the approach used to identify the needed water system facilities, the resulting CIP, and the cost estimates.
- Section 7 develops the water demands, required water facilities, and their costs for the Baseline scenario.
- Sections 8 develops the same information for the Plan Area scenario.
- Appendix A contains back up information for the development of the demand factors.
- Appendices B, and C contain the supply capacity, use of supply, comparison to demand, and storage evaluations for the Baseline and Plan Area scenarios.
- Appendix D has the cost estimate tables for each CIP project.

Section 2

Existing Water System Description

This section describes SCWA's existing Zone 40 water system. It contains a description of the water supply facilities including surface water facilities, groundwater wells, storage tanks, pressure zones, and the piping system. Recycled water facilities are also described.

2.1 Surface Water Facilities

SCWA surface water supplies for Zone 40 are diverted from the Sacramento River at Freeport and through the City of Sacramento's (City) Sacramento River SWTP.

Surface water diverted from the Sacramento River at the Freeport diversion structure is conveyed through the Freeport Regional Water Authority (FRWA) pipeline, treated at the Vineyard SWTP, and then delivered to the Zone 40 service area. FRWA was created as a joint powers authority (JPA) between SCWA and East Bay Municipal Utility District (EBMUD) in 2002, to increase surface water supply to the southern part of Sacramento County to reduce the county's dependence on groundwater through the implementation of a conjunctive use program and to provide a dry year surface water supply for EBMUD.

In 2011, FRWA completed the Sacramento River diversion at Freeport and a conveyance pipeline. The 84-inch (in) diameter pipeline with a capacity of 170 million gallons per day (mgd) starts at the Freeport intake, crosses Interstate 5 and Highway 99 to the east, and then parallels Gerber Road to a bifurcation at Vineyard Road. A SCWA owned 60-in diameter pipeline with a capacity of 70 mgd then conveys water north from this point to the Vineyard SWTP, which is located in the CSA. An EBMUD owned 66-in diameter pipeline with a capacity of 100 mgd continues further east to the Folsom South Canal.

The current permitted capacity of the Vineyard SWTP is 60 mgd with an ultimate capacity of 100 mgd. Treatment facilities include coagulation, flocculation, sedimentation, filtration, and chlorine disinfection. The plant is also provided with solids-handling facilities. Other facilities include a clear well / chlorine contact tank, an electrical building, and treated water pump station.

The Vineyard SWTP currently provides treated surface water to customers in the CSA, SSA, and NSA. Three pipelines cross Highway 99 and hydraulically connect the CSA and the SSA at Sheldon Road, Bond Road, and Grant Line Road. The Sheldon Road pipeline was constructed in 2010. Treated water from the Vineyard SWTP is conveyed to the NSA through the Phase A NSA pipeline that was constructed in 2018.

Surface water can also be provided to the SSA through the Franklin Intertie, but this intertie has not been used as a source of surface water supply in recent years. The City could divert and treat a portion of SCWA's surface water at their Sacramento River SWTP, and then wheel that water through their distribution system to the Franklin Intertie to Zone 40. The Franklin Intertie has a capacity of 11.1 mgd. Water from the intertie can flow into the SSA though two routes. A dedicated transmission main connects to SCWA's Dwight Road facility where the supply can be pumped into the SSA. Water from the intertie can also be supplied to the SSA through an in-line booster pump that connects directly to the SSA distribution system.

Table 2-1 summarizes the surface water facilities' capacities.

Table 2-1. Zone 40 Surface Water Facilities						
Facility	Treated Water Capacity, mgd	Storage Tank Volume, MG	Pump Station Capacity, mgd			
Vineyard SWTP	50/100 ultimate	20	75 mgd			
Franklin Intertie	11.1		1.6a			

a. This is the capacity of the in-line booster pump near the intertie. Franklin Intertie supply can be pumped to the SSA through either the Dwight Road GWTP booster pump station facility or the in-line booster pump.

2.2 Groundwater Facilities

Groundwater is supplied to Zone 40 from wells that that are connected to groundwater treatment plants (GWTPs) and from wells that pump directly into the distribution system (direct feed).

Each GWTP facility consists of wells that are manifolded into a treatment plant, a ground level storage tank, and a pump station. Most GWTPs are supplied by more than one well. The existing GWTPs use oxidation and filtration with a manganese zeolite (greensand) filter media for iron and manganese treatment. Treated water from the GWTPs flows into the ground level storage tanks and is subsequently pumped into the distribution system. The pump stations are typically sized larger than the GWTP capacities so that peak hour or fire flow supply can be pumped to the distribution system from the storage tanks. In the case of the Dwight Road GWTP in the SSA, the pump station is sized larger than the GWTP to also pump the Franklin Intertie supply into the SSA. Storage tanks that are not located at a GWTP facility are described in Section 2.3.3.

The direct feed wells pump directly into the distribution system and do not require treatment. Direct feed wells are located in some areas of the CSA and SSA. SCWA also has some wells that were drilled and planned to be equipped in the future. Because these wells are not currently equipped to provide a groundwater supply to the system, they are not included in this section.

The wells used to feed the Anatolia GWTP are located in the CSA near the Vineyard SWTP, while the GWTP is located in the NSA and the treated water is supplied to the NSA. The wells that supply the GWTPs, storage tanks at the GWTPs, and pump stations in the NSA are listed in Table 2-2. There are no direct feed wells in the NSA. The locations of these facilities are shown on Figure 2-1.

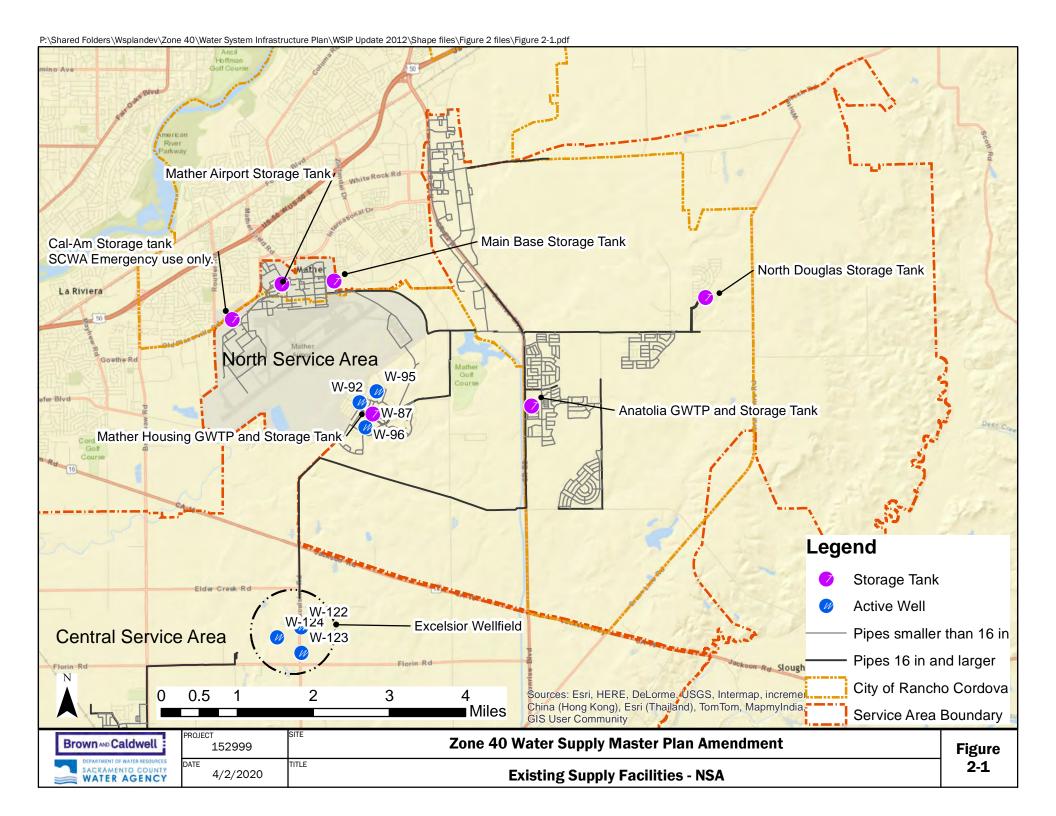

Table 2-2. NSA Groundwater Facilities							
		Well Capacity		Storage Tank	Pump Station		
Facility	GWTP Capacity, mgd	Wells to GWTP, gpm	Direct Feed Wells, gpm	Volume, MG	Capacity, gpm

Total	12.5	10,150		4.5	11,400 (16.4 mgd)		

a. The pump station pumps a portion of the supply from the tank. The remaining supply is fed by gravity to Mather Housing.

The CSA is supplied water from the Vineyard SWTP and five groundwater treatment plants. There are also three direct feed wells that supply the CSA. The GWTPs, wells that supply the GWTPs, direct feed wells, storage tanks at the GWTPs, and pump stations in the CSA are listed in Table 2-3. The locations of these facilities are shown on Figure 2-2.

Total	30.5		2,700	14.4	48,700 (70.1 mgd)

The SSA is supplied water from four GWTPs and from the Franklin Intertie. There are also six direct feed wells that supply the SSA. The SSA also receives some supply from the CSA. The GWTPs, wells that supply the GWTPs, direct feed wells, storage tanks at the GWTPs, and pump stations in the SSA are listed in Table 2-4. The locations of these facilities are shown on Figure 2-3.

	Table 2-	4. SSA Groundwa	ter Facilities

a. Dwight Road GWTP pump station capacity is sized to also pump the supply from the Franklin intertie into the SSA distribution system.

2.3 Water Distribution Facilities

Existing water distribution facilities within Zone 40 include storage tanks and pipelines. The system is also comprised of several pressure zones.

2.3.1 Pressure Zones

Zone 40 consists of two pressures zones, as described below. Figure 2-4 provides a hydraulic schematic of the Zone 40 system that illustrates the pressure zones and ground elevations of key water distribution and supply facilities. Table 2-5 summarizes the ground elevation and maximum day pressure range by pressure zone from SCWA's hydraulic model.

- NSA Main Zone The NSA Main Zone is the largest pressure zone within the NSA. The NSA Upper Zone will be added in the future.
- CSA/SSA Zone The CSA and SSA form one pressure zone that is hydraulically connected by three pipelines that cross Highway 99.

Table 2-5. Pressure Zones						
Pressure zone	Ground Elevation Range, ft	Maximum Day Pressure, psi				
NSA Main Zone	74 to 215	40 to 85				
CSA/SSA Zone	10 to 96	50 to 75				

2.3.2 Pipelines

Table 2-6 summarizes the existing transmission and distribution pipeline length by pipe diameter in each of the service areas. SCWA defines transmission pipe to be those 16 inches in diameter and greater. This includes SCWA pipelines within the Elk Grove wholesale area and raw water pipelines that connect the groundwater wells to the GWTPs.

Table 2-6. Distribution Pipeline Length by Diameter by Service Area						
Diameter,		Pipe Lengtl	h, linear feet			
inch	NSA	CSA	SSA	Total		
Distribution						
<8-in	54,200	200	10,600	65,000		
8 to 10-in	264,300	421,700	1,080,200	1,766,200		
12 to 14-in	128,800	175,700	344,100	648,500		
Transmission						
16 to 24-in	52,300	167,600	231,800	451,600		
30 to 36-in	47,100	34,300	16,200	97,500		
> 36-in	11,800	24,800	1,300	37,800		
Total	558,300	824,000	1,684,000	3,066,200		

2.3.3 Storage Facilities

Zone 40 has fourteen active storage tanks. Eleven of the storage tanks are located at GWTPs and described in Section 2.2. The three storage tanks that are independent storage facilities that are not part of a GWTP facility are listed in Table 2-7. These tanks are used to meet the peak hour increment of demand that is greater than the maximum day demand as well as emergency and fire flow demands. Cal Am has a 3 MG storage tank in the NSA that is available to SCWA for emergency purposes.

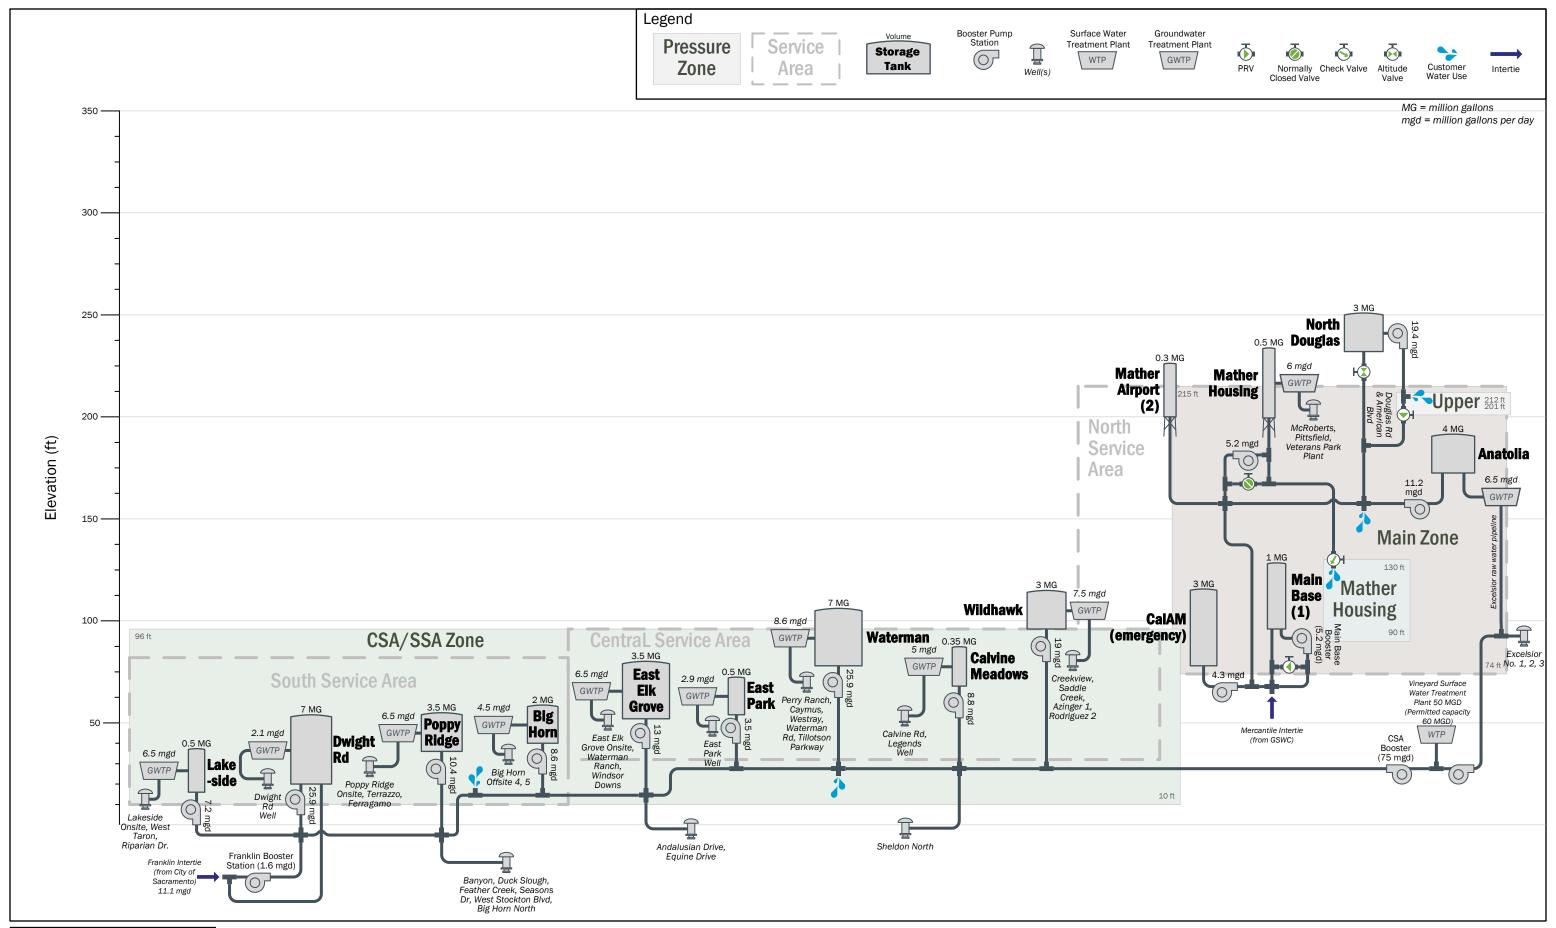

Table 2-7. Stand-alone Storage Facilities										
Name	Volume, MG	Pump Station Capacity, gpm	Pressure Zone							
Mather 1 storage (Main Base)	1.0	3,600 (5.2 mgd)	NSA Main Zone							
Mather 2 storage (Mather Airport)	0.3	Elevated tank	NSA Main Zone							
North Douglas	3.0	13,500 (19.4 mgd)	NSA Upper Zone							
Total	4.3									

2.4 Recycled Water Facilities

Beginning in 2003, the Sacramento Regional County Sanitation District (SRCSD) started wholesaling recycled water to SCWA for the Phase I SRCSD/SCWA Water Recycling Pilot Program (WRPP). The Phase 1 recycled water service area consists of the Laguna West, Lakeside, and Laguna Stonelake communities that are located in the western third of the Laguna planning subarea in the SSA. In these areas SCWA retails the recycled water to large commercial irrigation customers, industrial customers, right-of-way landscaping, schools, and parks.

Some of the Phase 2 recycled water conveyance facilities have been constructed in the East Franklin and Laguna Ridge planning subareas in the SSA. The portions of the system that are operational are using potable water as a supply source.

SRCSD is responsible for the collection, treatment, and disposal of wastewater throughout most of the urbanized areas of Sacramento County. SRCSD operates a 5 mgd tertiary treatment facility at their regional wastewater treatment plant that includes a pump station. Recycled water is conveyed from the treatment facility via a single 24-inch transmission main than then drops to a 20-inch pipeline to the Phase 1 service area. The recycled water is then conveyed through a branched network of recycled water distribution pipelines ranging from 8-inch to 14-inch diameter in size.

Section 3

Water Demands

This section presents the historical water use, the methodology used to develop future water demands, the connection growth projection, and the water demand factors. The projected water demands for the various scenarios are presented later in this document.

3.1 Historical Connections and Water Production

This section describes the historical number of connections, and the analysis to develop the projected demographics at buildout as well as the resulting projected growth rates of connections and population for Zone 40. Following the completion of SCWA's 2010 UWMP, the 2010 census data became available. An analysis of the 2010 population served by Zone 40 based on the 2010 census was performed (Brown and Caldwell, 2012). The historical number of connections by service area within Zone 40 is shown on Figure 3-1.

Figure 3-1. Historical connections by service area

Note: Connections in Elk Grove wholesale area are not included on this figure because of unavailable historical information for all of the years depicted.

Historical potable and recycled water production in Zone 40 from 2001 to 2019 by service area is shown in Table 3-1 and illustrated on Figure 3-2. The production quantities presented in Table 3-1 for the three service areas differ from the water demands in these service areas since some of the water produced in the CSA is utilized in the SSA. Portions of the SSA's and NSA's water demands have been supplied by water from the CSA that has increased with the start-up of the Vineyard SWTP in 2011 and the construction of the Phase A NSA pipeline in 2018, as described in Section 2.1.

a. Historical production provided by SCWA staff.

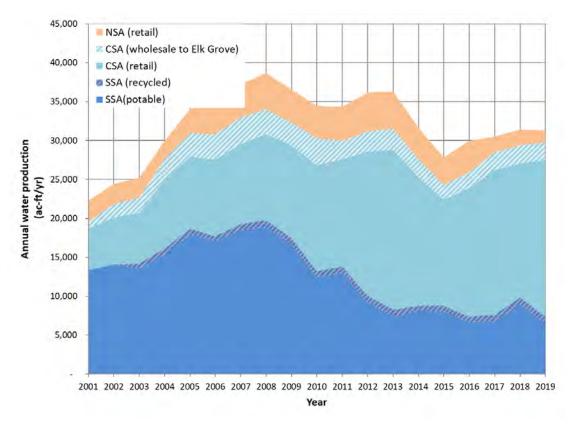

Figure 3-2. Historical annual water production by service area

3.2 Water Demand Projection Methodology

Water demands are estimated based on the water demand estimate analysis progression shown on Figure 3-3. The approach has two components, which are the demographics and the water demands.

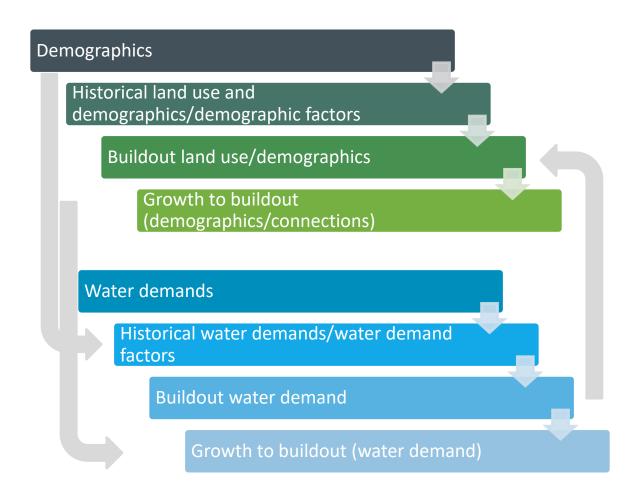

Figure 3-3. Water demand estimate analysis progression

The first part of the process is focused on land use and demographics. Demographics consist of population, connections, and dwelling units (DUs). The 2010 developed land use acreage by type of use is used to establish demographic factors such as connections and dwelling units per acre. The buildout developed land use acreage is then used to estimate buildout demographics. Buildout is considered to be reached when the available land is fully developed up to the maximum allowed for each land use category.

The number of dwelling units at buildout is estimated based on the maximum number of DUs allowed per acre in each of the general plan residential land use categories multiplied by the number of acres. The projected number of DUs at buildout is used to estimate the number of buildout residential connections and population. The buildout population for Zone 40 is estimated using a population per DU factor from the 2010 population and DU census data. Following the completion of SCWA's 2010 UWMP, the 2010 census data became available. An analysis of the 2010 population served by Zone 40 based on the 2010 census was performed (Brown and Caldwell, 2012). The number of residential connections at buildout is based on the maximum DUs /acre allowed for residential land uses and assumed DUs per connection factors. The estimate of the Zone 40 buildout population was used in SCWA's 2015 Urban Water Management Plan.

For non-residential land uses, the number of connections at buildout is more speculative because of the uncertainty of the mix of types and land area sizes of industries, businesses, parks, and other public facilities. For public land uses the size of parks and public facilities will influence the number of connections in that category. The number of connections at buildout is estimated assuming that the number of connections per acre would be 20 percent higher than the 2010 value. The projected annual connection growth for each service area is estimated.

The second part of the process consists of developing water demand factors based on the historical water use compared to the amount of developed areas, population, and DUs. These historical demand factors are used to develop the demand factors projected for buildout. The buildout demand factors are then used together with the buildout land use and demographics to estimate the buildout water use. The increase in demand to buildout for each service area is based on the projected increase in connections for each service area.

The information presented in this report typically includes all of SCWA's retail service area, the Elk Grove wholesale area, and the future Cal Am wholesale area in Rio del Oro. In the instances where the information excludes the Elk Grove wholesale area, it is so noted.

3.3 Land Use

This section describes the planning subareas, land use, and residential density.

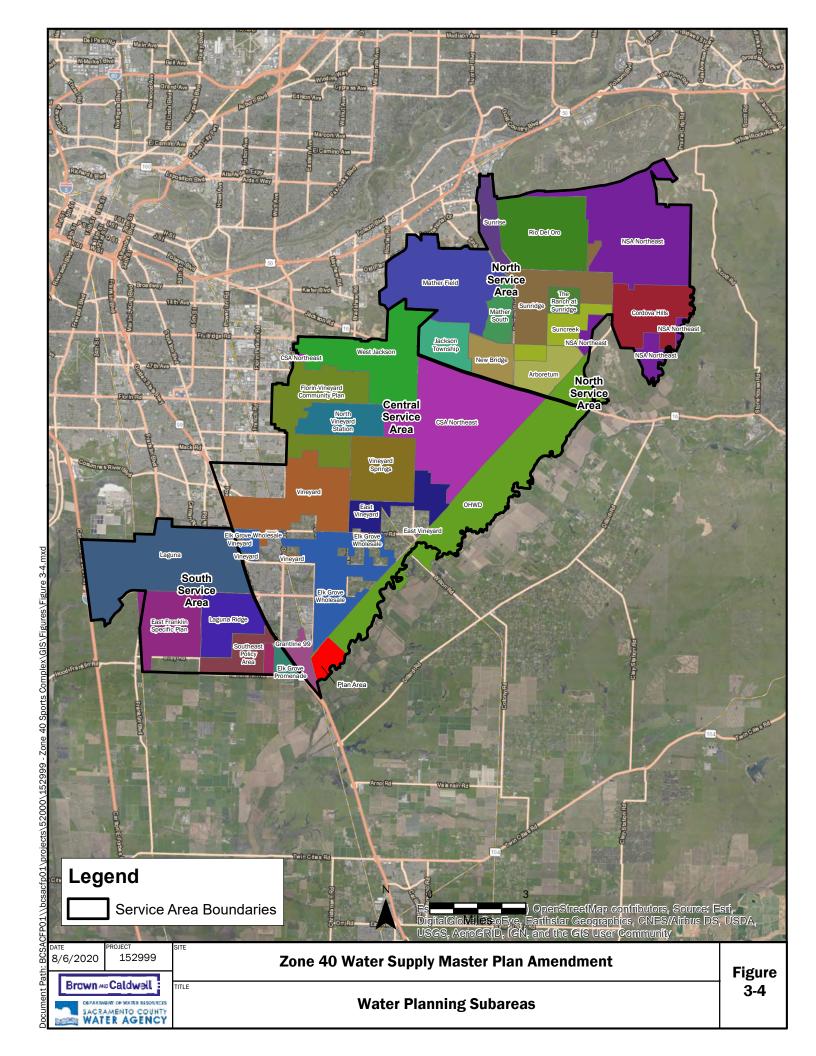

3.3.1 Planning Subareas

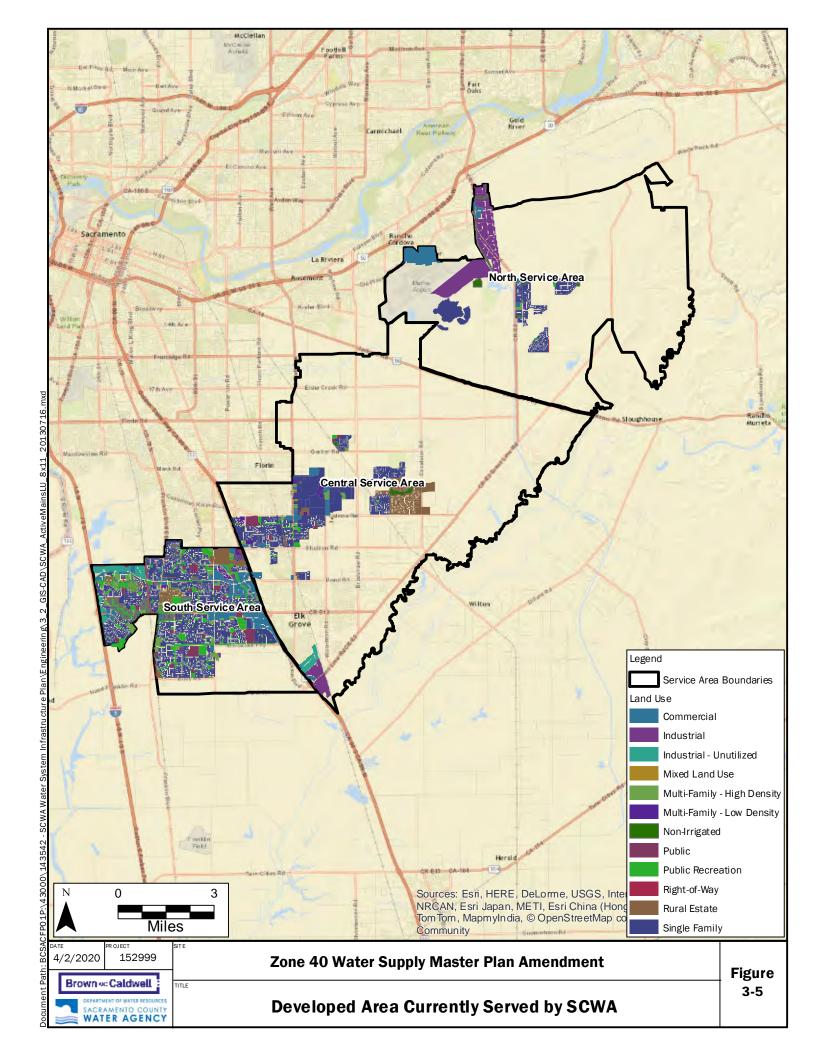

The study area is divided into planning subareas. The boundaries of the subareas correlate to current city boundaries, unincorporated areas, communities, and new growth areas defined by future development plans. The subareas are grouped into the three Zone 40 service areas: NSA, CSA, and SSA. The location of these subareas is illustrated on Figure 3-4.

3.3.2 Land Use

The area of land that was served by SCWA in 2010 is illustrated on Figure 3-5. The shaded areas on Figure 3-5 represent the area of land developed in 2010 and served retail water by SCWA. Figure 3-5 does not include the portion of Elk Grove Water District that is served by SCWA wholesale water supply. The 2010 developed acreage was estimated based on the location of SCWA's existing retail water distribution piping system. The 2010 land use was used as the basis of developing the population and water demands in SCWA's 2015 Urban Water Management Plan and the pending Water Supply master Plans for the new growth areas. The amount of development since 2010 was smaller then previously predicted due to the recession.

GIS maps of the land uses defined by the most recent land use planning information for Sacramento County, the City of Elk Grove, and the City of Rancho Cordova, as well as maps of the proposed developments in the new growth areas were used to quantify the area of each land use category within each planning subarea. The land use categories presented in the general plans have been collapsed into a reduced set for the purposes of this analysis. The 2010 land use acreages by land use category are summarized in Table 3-2.

Gross acres are defined as the total land area for each land use category including streets and right of way areas. Net acres exclude the area occupied by streets and right of ways. It is assumed that streets and right of ways cover 20 percent of the gross area within the residential, commercial, and industrial land use categories. All other land use categories are assumed to not have streets and right of ways, so their net and gross acreages are the same. The acreages presented in Table 3-2 are net acres.

The buildout gross acreage presented later in this report was estimated based on GIS data that included areas of both net and gross acreage. For those areas where the GIS data was provided as net acreage, the quantity of net acres was converted to gross acres.

Table 3-2. 2010 Area By Land Use						
Land Use Category	2010 Developed Area, Net Acres					
Rural estate	1,380					
Single family	6,970					
Multi-family - low density	220					
Multi-family - high density	390					
Commercial	1,520					
Industrial	1,110					
Industrial-unutilized	340					
Public	920					
Public recreation	1,270					
Mixed land use	20					
Right-of-way	70					
Subtotal, municipal water supply land area	14,210					
Self-supported/supplied by others	-					
Non-irrigated	500					
Agricultural	-					
Total	14,710					

Note: Elk Grove wholesale area is not included in the 2010 developed area acreage because it was not available.

3.3.3 Residential Land Use Density

The general plan residential land use categories each have a DU density range in terms of the minimum and maximum allowed number of DUs per acre. The buildout DUs and resulting residential water connections developed in this analysis are based on the maximum density allowed within each land use category (i.e. 7 dwelling units/acre for the RD 5-7 land use category). Each of the four residential land use categories defined for this analysis represent several general plan residential land use categories. The average and maximum dwelling unit densities established for each of the four residential land use categories were developed using the weighted average by buildout acreage of the several land use types represented in each category. Actual land use density at buildout may vary from what is assumed in this document.

Another density variable is bonus density. In general, bonus density is an increased DU density above and beyond the maximum allowable residential density under the local zoning ordinance. Section 65915 of the Government Code requires that local government provide a developer with incentives or concessions for increasing the production of housing units and child care facilities when an applicant seeks a density bonus for a housing development or for the donation of land for housing within the county. In 2004, Senate Bill (SB) 1818 amended section 65915 of the Government Code, pertaining to the density bonus law. The purpose of SB 1818 is to encourage developers to build affordable housing by requiring local governments to provide meaningful incentives. The projected number of DUs has not been adjusted for the possibility of bonus density being provided.

3.4 Connection Growth Projection

The future growth rate of Zone 40 is expressed as the growth in the number of water system connections. The growth in water system connections is projected based on an evaluation of the range of historical growth trends that have occurred in each service area. Figure 3-1 depicts the number of historical connections for the 2001 to 2019 period. Because of the uncertainty in the future rate of growth, three growth rates were developed in the 2016 WSIP and expressed as low, medium, and high. The medium growth rate is used for the projections in this document. The low and high connection growth rates are approximately the same as the lowest (1,300 connections per year) and highest (3,600 connections per year) historical 5-year moving average growth rate for the 9 year period from 2001 to 2010. The medium growth rate begins at 1,000 new connections per year increasing to 1,500 new connections per year in 2020 and thereafter until buildout. The connection growth rate projection is not revised for this WSMP amendment. The number of new connections estimated to occur each year for each service area is presented in Table 3-3. The connection growth rate to 2024 was provided by SCWA staff. Any change in the growth of new connections to the water system will change the water demand projection.

Table 3-3. Projected Annual Connection Growth (new connections) ^{a b}								
Year	NSA	NSA CSA SSA						
2020	500	500	500	1,500				
2021	500	500	500	1,500				
2022	500	500	500	1,500				
2023	500	500	500	1,500				
2024	500	500	500	1,500				
2025	500	500	500	1,500				
2030	500	500	500	1,500				
2031	600	600	299	1,499				
2035	750	750	-	1,500				
2040	750	750	-	1,500				
2045	750	750	-	1,500				
2050	750	750	-	1,500				
2051	750	15	-	765				
2052	659	-	-	659				

Note: Annual growth is shown from 2020 to 2025. Years after 2025 are shown in 5-year intervals and for years when buildout within a service area occurs. Annual growth for years not shown between 5-year intervals is constant.

- New connections include the Elk Grove wholesale subarea, Cal Am portion of Rio Del Oro subarea, and recycled water connections.
- b. Connection growth rate to 2024 was provided by SCWA staff.

3.5 Unit Water Demand Factors

Buildout unit water demand factors (UWDFs) are developed using a water demand per land area approach expressed as ac-ft/yr per acre. The buildout water demands are estimated by combining the buildout land use acreage for each type of land use with the applicable buildout UWDFs. This land area based approach for developing the buildout water demands is the same methodology used in the 2006 WSMP and the subsequent Cordova Hills amendment. Due to changes in water use characteristics, the 2016 WSIP included an update of the UWDFs. The updated UWDFs were used for the demand projections presented for Zone 40 in SCWA's 2015 Urban Water Management Plan. The UWDFs are not revised for this WSMP amendment. The buildout UWDFs were updated in the 2016 WSIP based on consideration of several sources of information as described below.

- 2005 WSMP UWDFs: The UWDFs in the 2005 WSMP, which are assumed to be gross factors (applied to gross acreage) (SCWA, 2005).
- Cordova Hills WSMP Amendment: The UWDFs for buildout in the 2005 WSMP were verified with limited meter data (SCWA, 2011).
- SCWA analysis of residential water use: SCWA conducted an analysis of metered residential
 connections in Zone 40 and developed UWDFs for rural residential, single family, multi-family
 low density, and multi-family high density land uses for the years 2005 through 2012 (SCWA,
 2013). The analysis showed a reduction in the UWDFs since the previous work was completed.
 This analysis is presented in Appendix A.

- Analysis of SCWA 2010 Water Use Factors: UWDFs representing 2010 using 2010 estimated developed acreage in Zone 40 and SCWA water use data by customer category.
- 2010 UWDFs of other water agencies: The water demands per acre for other local water agencies were analyzed to use as a point of comparison.
- Gallons per capita per day (GPCD): In July 2011, SCWA adopted the 2010 UWMP, which included
 an analysis and selection of the SBx7-7 GPCD goal for all of SCWA's service areas. To meet
 SCWA's GPCD goal established in the 2010 UWMP of 222 GPCD for all of its service areas, the
 Zone 40 GPCD target for 2020 was 196 GPCD. The Zone 40 per capita demand was less than
 the target in 2010.
- In June 2016, SCWA adopted the 2015 UWMP, which included revising SCWA's 2020 target for all of its service areas from 222 GPCD to 236 GPCD. Therefore, the Zone 40 portion of the 2020 target would be a value greater than 196 GPCD.

It's recognized that unit water use on a per capita basis has been trending downward for several years. The analysis of 2005 to 2012 residential water use by SCWA showed marked reductions in the water use per acre, which was also evident in the analysis of 2010 demand conducted for this study. Water use declined further from 2014 to 2016 as a result of the Governor's drought declaration. Although water use has increased in recent years since the end of the drought, it has not returned to pre-drought levels. The evaluation of water demand characteristics has not been updated for this WSMP amendment.

The UWDFs for the non-residential water use categories have some uncertainty due to the unknown water use characteristics of future non-residential development. There can be a wide range in water use by different types of non-residential development. It is recommended that as non-residential development occurs in the future, the water use of that new development be monitored and tracked along with the specific type of development and the amount of acreage occupied. Table 3-4 compares historical and projected water use metrics including demand per capita, per dwelling unit, per connection, and per acre for Zone 40. Below are some observations regarding some of the factors with the larger change ratios between 2010 and buildout.

- Non-residential water use/dwelling unit factor almost doubles from 2010 to buildout. This reflects the large increase in the amount of non-residential land area and resulting water use compared to the projected increase in residential land area.
- Non-residential use/non-residential connection factor increases by 20 percent from 2010 to buildout. This reflects the change in the mix of non-residential land use categories. One example is the proportionally large increase in public land use acreage at buildout. The public recreation land use category has connections that serve larger parcels and have a higher UWDF compared to the other non-residential land use categories.

Table 3-4. Zone 40 Comparison of 2010 to Buildout Water Use Metrics							
	2010	Buildout	Change ratio				
Gallons per capita per day ^a	186	189	1.02				
Total use/total DU, gpd/DU	570	572	1.00				
SFR use/ SFR DU, gpd/DU	490	474	0.97				
MFR use/MFR DU, gpd/DU	119	174	1.46				
Non-res use/DU, gpd/DU	102	188	1.84				
Total use/total con, gpd/connection	606	870	1.43				
SFR use/SFR con, gpd/connection	490	474	0.97				
MFR use/MFR con, gpd/connection	2,734	2,003	0.73				
Non-res use/non res con, gpd/connection	2,856	3,457	1.21				
Total demand per developed acre, ac-ft/ac	2.10	2.20	1.05				
Potable demand per developed acre (recycled water removed), ac-ft/ac	2.05	2.13	1.04				

SFR=single family residential

MFR=multi-family residential

Note: Water loss of 7.5% of water sales is included in this table.

The gross unit water demand factors are listed in Table 3-5. These UWDFs should be applied to gross acreage that has not been adjusted to remove streets or right-of-way. Water system loss is not included in the UWDFs.

Table 3-5. Buildout Unit Water Demand Factors						
Land use	Gross Unit Water Demand Factors ^a , ac-ft/acre/yr					
Rural estate	1.37					
Single family	2.13					
Multi-family - low density	2.44					
Multi-family - high density	3.33					
Commercial	2.02					
Industrial	2.02					
Public	0.81					
Public recreation	2.80					
Mixed land Use	2.15					
Right-of-way	0.18					
Self-supported/supplied by others						
Non-irrigated						
Industrial-unutilized						
Agricultural						

a. Water loss is not included in the unit water demand factors.

a. Includes recycled water. Therefore, the GPCD value excluding recycled water is a smaller value. GPCD for purposes of reporting to the California Department of Water Resources does not include recycled water.

Water loss includes water loss due to leaks, breaks, storage overflows, water use for firefighting, line flushing, and other authorized, but unbilled uses. Since SCWA is not completely metered, data are unavailable for determining the current percent of water loss. Water loss is assumed to 7.5 percent of water sales.

3.6 Recycled Water Demands

Recycled water use is currently approximately 900 ac-ft/yr. Recycled water use is projected to increase to a total of 3,300 ac-ft/yr when the planned Phase 2 recycled water system for the East Franklin and Laguna Ridge areas is completed.

The potential for additional recycled water use in areas in close proximity to the existing and planned Phase 1 and 2 areas are estimated to be approximately 500 ac-ft/yr based on serving public and public recreation land use categories in the adjacent subareas. This analysis of additional potential recycled water demand is not a recommendation to supply recycled water to these areas.

This page intentionally left blank.

Section 4

Water Supply

The sources of water for SCWA's Zone 40 consist of surface water, groundwater, and recycled water. The existing water supply sources are described and quantified in this section. The adequacy and reliability of each supply for normal and dry hydrological conditions are presented.

4.1 Water Forum Agreement

SCWA is a stakeholder in the Water Forum, a Sacramento regional water management initiative. The Water Forum Agreement (WFA) was the result of the efforts of a diverse group of community organizations formed in 1994 to formulate principles for a regional solution for protecting the lower American River and providing for future water supply. The WFA was designed to achieve the two coequal objectives of providing a reliable and safe water supply for the region's economic health and planned development to the year 2030 and preserving the fishery, wildlife, recreational, and aesthetic values of the lower American River.

The WFA includes purveyor specific agreements (PSA) that define the benefits each water purveyor will receive as a stakeholder and actions each water purveyor must take to receive these benefits. The PSA for SCWA discusses the planned surface water supplies as part of a conjunctive use program to meet SCWA's water needs for planned growth. The PSA says that SCWA will divert surface water at or near the mouth of the American River or from the Sacramento River. Pertinent elements of the PSA for SCWA are discussed in the surface water and groundwater supply descriptions in this section.

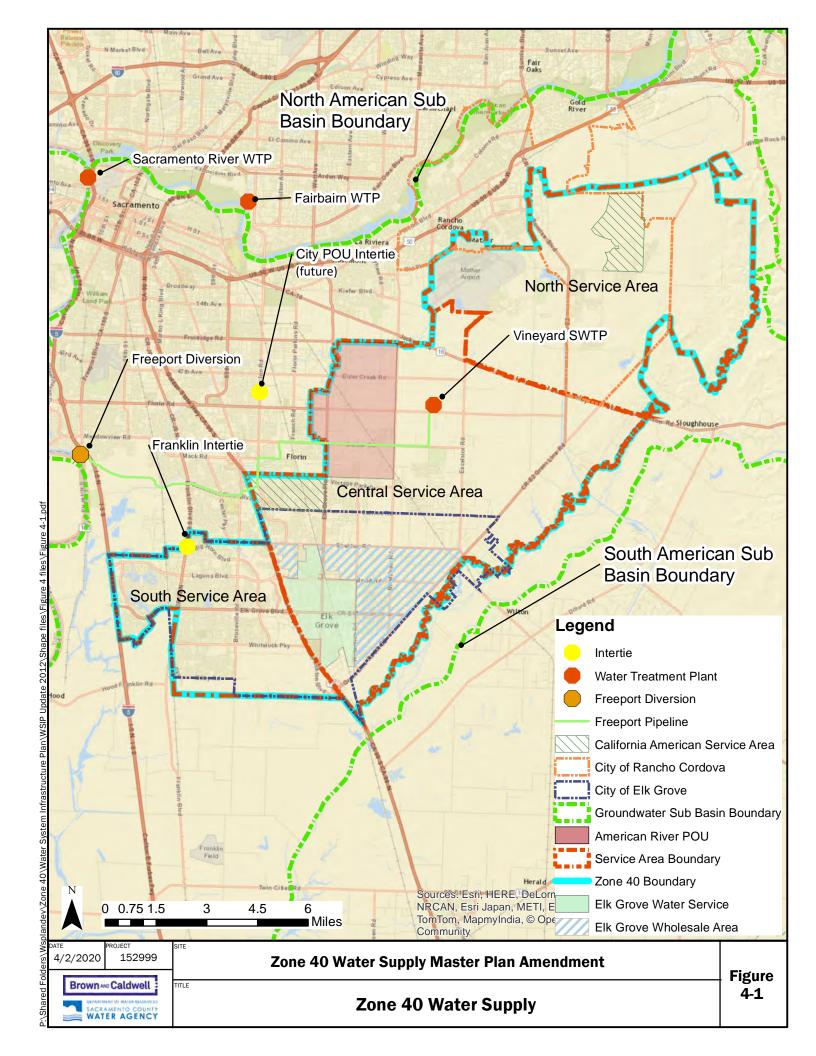

The WFA was most recently updated in October 2015. Major changes include: incorporation of Arcade and Northridge Water Districts into the Sacramento Suburban Water District PSA, execution of the Golden State Water Company PSA (formerly Arden Cordova Water Services), renegotiation and ratification of the California American Water Company PSA, and changes to the Water Conservation Element and Water Forum Successor Effort Decision-Making Process as a result of a multi-year negotiation among Water Forum members. The Water Forum initiated a process to renegotiate the WFA in 2020.

4.2 Surface Water

Zone 40 surface water supplies consist of Central Valley Project (CVP) water, appropriative water, American River Place of Use (POU) water, and other surface water sources. Figure 4-1 illustrates the location of the major surface water facilities.

The quantities of surface water available to SCWA in wet/average, drier, and driest years and the frequency of their occurrence are important aspects for the planning of a conjunctive use system. The availability of each surface water supply source in different water year types is described below.

4.2.1 Central Valley Project Water

SCWA has two repayment contracts with Reclamation - the "Fazio" Contract which is for 15,000 ac-ft/yr and the Sacramento Municipal Utilities District (SMUD) Contract which is for 30,000 ac-ft/yr with the recent renegotiation which was completed in early 2020. The CVP water is diverted at the Freeport diversion on the Sacramento River and treated at the Vineyard SWTP. The CVP supplies can also be diverted from the Sacramento River and treated at the City's Sacramento River SWTP and delivered to SCWA at the Franklin Intertie.

SCWA's total CVP supply is subject to reductions in dry years. The water supply allocations are defined by Reclamation on a year to year basis and are expressed as a percentage of either the contract amount or amount of the most recent three year average use, whichever is the lower value. SCWA does not divert its full contract amount, so the supply allocation is applied to the amount of average annual use. For the 20 year period of 1995 to 2014, the lowest allocation was 50 percent in 2014. In 2015, the north of Delta allocation to urban contractors was 25 percent of historical use, which was the lowest allocation on record. The consequence for SCWA was that the CVP supply was fully curtailed for several months during the summer.

The water supply allocations are based on a draft policy that defines water shortage terms and conditions. Reclamation initiated the development of a Municipal and Industrial (M&I) Water Shortage Policy in 1992, with several proposals prepared through 2001. The 2001 draft water shortage policy states that Reclamation would reduce M&I water to a contractor once irrigation water allocations are reduced below 75 percent of the contract amount. Reclamation has a provision in the draft policy for a minimum M&I shortage allocation of 75 percent that is applied to the last three years of historical use with certain adjustments, although the actual allocation in 2014 was 50 percent of historical use (US, 2001). In 2010, Reclamation convened several workshops that will lead to the development of an Environmental Impact Statement that could potentially modify the existing policy or develop a new policy (US, 2011).

Supply allocations of 100 percent in a wet and average year, 75 percent for a drier year, and 50 percent of the historical use in the driest year are assumed. This WSMP amendment does not revise the driest year supply allocation to reflect the 2015 experience.

4.2.2 Appropriative Water

In February 2008, the State Water Resources Control Board (SWRCB) approved SCWA's appropriative right permit application to divert water from the American and Sacramento Rivers (Permit 21209). The amount of appropriated water available for use could range up to 71,000 acft/yr in wet years, primarily during the winter months. This water would be diverted at the Freeport diversion on the Sacramento River. Since SCWA's demands are low in the winter months, SCWA would likely have to construct storage to utilize the full amount. It is possible that 35,000 ac-ft/yr of this supply could be utilized without the ability to store the water. No supply from this source is assumed for the drier and driest years.

4.2.3 City of Sacramento's American River Place of Use Water Supply

A portion of Zone 40 lies within the City's American River POU. The City has a pre-1914 water right to the American River with a POU boundary that extends beyond the City's boundary and includes a

portion of Zone 40, as shown on Figure 4-1. The amount of water available to serve the POU area within Zone 40 is estimated to be 9,300 ac-ft/yr (SCWA, July 2011).

The Water Forum PSA for SCWA assumes that the City's American River water entitlements would be a source of supply for Zone 40. This is consistent with the City's PSA. The City is planning for the wholesale delivery of American River water within the POU including areas outside of the City limits. A connection would be constructed to supply the Florin Vineyard Community Plan area in the CSA, with the timing based on when the supply is actually needed.

The City's diversions from the American River at the Fairbairn Water Treatment Plant are reduced when American River flows are less than the Hodge Flow Criteria, which would likely result in no POU water being available for SCWA in these circumstances. The City may decide to divert water during these restricted times at their Sacramento River diversion, although additional infrastructure might need to be constructed by the City to be able to convey this water to SCWA. It might be possible for SCWA to divert the POU water at the Freeport diversion. Given the uncertainty of the availability of POU water during dry periods, a supply allocation of zero percent in the driest year and drier year, and 100 percent in the wet and average year is assumed.

4.2.4 Other Water Supplies

Other water supplies are water transfers that would be obtained from various water users that hold surface water rights on the Sacramento River and the American River upstream of SCWA's point of diversion. To obtain these supplies, SCWA would enter into purchase and transfer agreements with other entities that hold surface water rights. There are Sacramento River water supplies available for transfer in dry years, although the costs of these dry year supplies can exceed \$500 per ac-ft.

The assumed quantity of other water supplies is 9,600 ac-ft/yr in dry years and no supplies transferred in wet years. The annual supply to demand comparison presented in Section 5.2 indicates that these other water supplies would not be needed at all if the CVP, POU, and groundwater supply amounts are not less than assumed. Therefore, the amount of other water supplies that would be needed would vary depending on the water supply situation.

SCWA has a Memorandum of Understanding dated April 2000 with GSWC to purchase up to 1,000 gpm of water through the Mercantile Intertie located within the NSA. The intertie between the two systems currently serves as an emergency connection for both water purveyors. No routine water supply from GSWC is assumed.

4.2.5 Summary of Surface Water Supplies

Table 4-1 presents SCWA's surface water supplies for the wet/average years, drier years, and driest years assuming no constraint on supply capacity. The long-term average supply values presented in Table 4-1 assume that the supplies are all fully utilized with no infrastructure capacity constraints for all of the water year types, except for the amount of appropriative water as described in Section 4.2.2. The frequency of occurrence of these water year types are assumed to be 64 percent, 28 percent, 8 percent of the years respectively, based on an analysis of a historical 70-year hydrologic period (SCWA, 2006, Pg. 7-3). The frequency of occurrence of different water year types may change in the future, such as due to the impacts of climate change.

Table 4-1. Summary of Surface Water Supplies, ac-ft/yr									
Water Supply Sources	Contract Water Right Transfer Amount	Wet Average Year	Drier Year	Driest Year	Long-Term Average ^a				
U.S. Bureau of Reclamation – CVP supply (SMUD 1, SMUD 2, and Fazio Water)	45,000	45,000	33,750b	22,500b	40,050				
Appropriative water – SWRCB Permit 21209	71,000	35,000	0	0	22,400				
City of Sacramento's American River POU Water Rights	9,300	9,300	0	0	5,952				
Other water supplies	9,600	0	9,600	9,600	3,456				
Total	134,900	89,300	43,350	32,100	71,858				

a. Based on full use of all supplies for each water year type, which is different than the projected actual use of supplies. The frequency of occurrence for the wet/average, drier, and driest years assumed to be 64 percent, 28 percent, 8 percent of the years respectively, based on an analysis of a 70-year hydrologic period (SCWA, 2006, Pg. 7-3).

4.2.6 Historical Use of Surface Water Supplies

The use of surface water in Zone 40 started in 1995 through a contract with Browns Valley Irrigation District. In 1999, delivery of the CVP contract water was started through a wheeling agreement with the City. Surface water has historically been a minor portion of the supply for Zone 40, as shown on an annual basis on Figure 4-2 and a monthly basis on Figure 4-3. The water supplies on Figure 4-2 are identified by the service area where the water production occurs. Some of the surface water and CSA groundwater produced in the CSA are used in the SSA. Surface water use in Zone 40 has increased starting in 2011 with the startup of the Vineyard SWTP.

b. CVP drier and driest year supplies are the lesser of these values or 75 and 50 percent of the three year historical average, respectively. The driest year CVP supply may be as low as 13,100 ac-ft/yr since the average year of use of the CVP supply will be lower than the contract amount for a number of years. The 25 percent allocation in 2015 is not reflected in the driest year value.

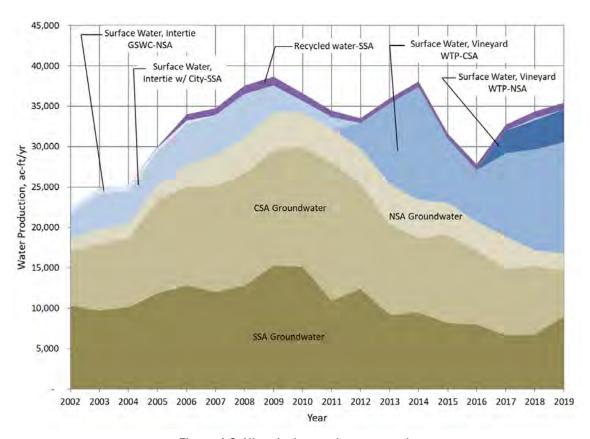

Figure 4-2. Historical annual water supply

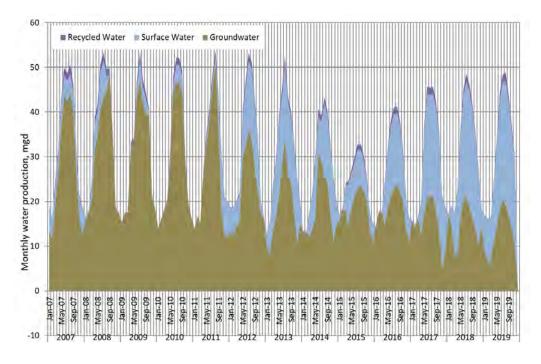

Figure 4-3. Monthly water production by type of supply

4.3 Groundwater

Groundwater is a major source of supply for Zone 40. This section describes the groundwater basin, the Sacramento Central Groundwater Authority (SCGA), historical groundwater use, and the remediated groundwater supply.

4.3.1 Groundwater Basin Description

Zone 40 is supplied groundwater from the South American Subbasin (5-21.65) that covers an area of 248,000 acres. The WFA, discussed in Section 4.1, divided the groundwater basin in Sacramento County into three portions as shown on Figure 4-4. The Central Basin's boundaries are similar to the boundaries of the South American Subbasin (5-21.65), although there are some differences. At this time there are active basin boundary modifications being considered by the state.

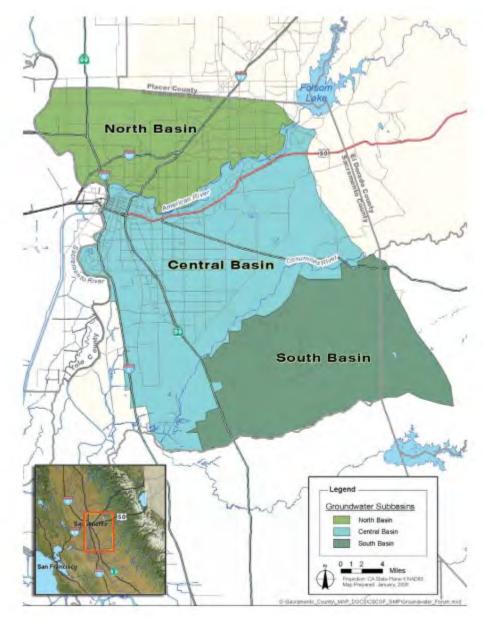

Figure 4-4. Sacramento County groundwater basins

The Central Basin is defined as the area bounded on the west by the Sacramento River, on the north by the American River, on the south by the Cosumnes River, and on the east by the foothills of the Sierra Nevada Range. The Water Forum defined the long-term sustainable average annual yield of the Central Basin to be 273,000 ac-ft/yr. Zone 40 lies within a portion of the Central Basin.

Groundwater in the Central Basin is generally classified as occurring in a shallow or upper unconfined aquifer zone (Laguna or Modesto Formation) and in an underlying deeper semi-confined aquifer zone (Mehrten Formation). These formations are typically composed of lenses of interbedded sand, silt, and clay, interlaced with coarse-grained stream channel deposits. The shallow aquifer extends approximately 200 to 300 feet below ground surface (bgs). The deep aquifer is separated from the shallow aquifer by a discontinuous clay layer that serves as a semi-confining layer for the deep aquifer. The base of the potable water portion of the deep aquifer averages approximately 1,400 feet bgs. Groundwater used in the Central Basin is supplied from both the shallow and deeper aquifer systems.

Intensive groundwater extraction from the Central Basin in the past has resulted in a general lowering of groundwater elevations near the center of the basin away from the sources of recharge. These depressions have grown and coalesced into a single cone of depression centered near Elk Grove. In recent years this depression has filled due in some part to the introduction of surface water into the area from the Vineyard SWTP. In general, the rest of the Central Basin does not show any distinctive patterns with respect to regional groundwater elevations, and the water table tends to mimic the local topography. Groundwater levels in the Central Basin have improved in recent years due to implementation of the conjunctive use program.

Groundwater in the upper aquifer system is of higher quality than that found in the lower aquifer system, although there are some occurrences of arsenic and nitrate. The lower aquifer system contains higher concentrations of iron and manganese and total dissolved solids (TDS). Water from the upper aquifer generally does not require treatment other than disinfection for public drinking water systems, unless high arsenic or nitrate values are encountered. Wells that pump from the lower aquifer often require treatment for iron and manganese. Most of SCWA's Zone 40 wells have iron and manganese treatment facilities.

Groundwater contamination plumes exist in the NSA that have migrated from the Aerojet/Boeing and Mather properties. SCWA has four operating wells (Mather Housing) in the vicinity of these plumes. There are several other smaller contamination plumes located in other areas of Zone 40. Significant remediation efforts/programs by federal, state, and local government agencies are in progress to clean up the contaminated groundwater and to confine the contaminant plumes from further spreading.

4.3.2 Sacramento Central Groundwater Authority (SCGA) and Groundwater Management Plan

SCGA was formed in 2006 through a joint powers agreement signed by the Cities of Elk Grove, Folsom, Rancho Cordova, and Sacramento, and the County of Sacramento. SCGA was formed for several purposes including maintaining the long-term sustainable yield of the Central Basin, managing the use of groundwater in the Central Basin, and facilitating the implementation of a conjunctive use program

The Central Sacramento County Groundwater Management Plan (CSCGMP), which was adopted in 2006 by SCGA, establishes a framework for maintaining sustainable groundwater resources in the Central Basin. This framework includes specific goals, objective, and an action plan to manage the basin and provides guidance to various stakeholders and negotiations for groundwater use. The

SCGA Groundwater Management Plan includes a detailed groundwater management implementation plan to comply with the requirements of their basin management objectives. Additionally, SCGA prepares a biennial report to evaluate progress on Groundwater Management Plan implementation and to report on basin conditions.

The Sustainable Groundwater Management Act (SGMA) was enacted by the legislature in 2014, with subsequent amendments in 2015. SGMA requires groundwater management in priority groundwater basins, which includes the formation of Groundwater Sustainability Agencies (GSAs) and the development of Groundwater Sustainability Plans (GSPs) for groundwater basins or subbasins that are designated by DWR as medium or high priority.

The designation of the priority of groundwater basins was done as part of the California Statewide Groundwater Elevation Monitoring (CASGEM) Program. CASGEM was developed in response to legislation enacted in California's 2009 Comprehensive Water package. The CASGEM Groundwater Basin Prioritization is a statewide ranking of groundwater basin importance that incorporates groundwater reliance and focuses on basins producing greater than 90 percent of California's annual groundwater. The CASGEM Program ranked the South American Subbasin (5-21.65) as high priority.

SGMA directs DWR to identify groundwater basins and subbasins in conditions of critical overdraft. DWR initially identified such basins in Bulletin-118, 1980 and Bulletin 118, Update 2003. DWR issued an updated draft list of critically overdrafted basins in July 2015 and in the most recent version in February 2018. The South American subbasin (5-21.65), that supplies Zone 40, is not on the list.

Groundwater basins designated as high or medium priority and critically overdrafted were required to be managed under a GSP by January 31, 2020. All other high and medium priority basins, including the South American subbasin, must be managed under a GSP by January 31, 2022. A GSA was required to be formally established by June 30, 2017. The GSA has enforcement authority over their designated portion of the basin.

SGMA also allows groundwater management agencies, within basins compliant with the CASGEM program, to prepare and submit an "alternative" to DWR instead of a GSP. An "alternative", in accordance with Section 10733.6 of the SGMA, was required to be submitted to DWR by January 1, 2017. In December 2016, the SCGA prepared and submitted an alternative submittal for the South American Subbasin in compliance with SGMA. The alternative was denied and SCGA is currently developing a GSP.

4.3.3 Historical Use of Groundwater Supplies

Groundwater historically has been a substantial portion of the supply for Zone 40, as shown on an annual basis on Figure 4-2 and a monthly basis on Figure 4-3. Completion of the FRWA project and the Vineyard SWTP and the resulting increased use of surface water have resulted in a reduction in the annual use of groundwater in Zone 40 since 2009.

The current groundwater pumping to meet agricultural demands within Zone 40 and each of the new growth areas is estimated at 12,730 ac-ft/yr for 4,050 acres based an inspection of aerial photographs to determine existing agricultural acreage for field and row crops and pasture.

4.3.4 Remediated Groundwater

SCWA has a remediated groundwater supply of 8,900 ac-ft/yr in accordance with the terms and conditions in the agreement entitled "Agreement between Sacramento County, SCWA, and Aerojet-General Corporation With Respect To Transfer of GET Water" dated May 18, 2010. The timing and

amount of remediated groundwater available is subject to change as a result of on-going negotiations with water purveyors affected by groundwater contamination and with Aerojet/Boeing as their remediation plans may change as directed by various regulatory agencies. The remediated groundwater is discharged into the American River from Aerojet's Groundwater Extraction and Treatment (GET) facilities located in the Rancho Cordova area that are used for groundwater cleanup operations. This remediated groundwater supply is diverted by SCWA from the Sacramento River at Freeport along with SCWA's surface water supplies. A supply allocation of 100 percent in the driest year, drier year, and in a wet and average year is assumed.

4.4 Recycled Water

Recycled water is tertiary treated wastewater obtained from SRCSD that is supplied to the SSA in Zone 40 as a source of non-potable water for irrigation of parks, schools, and rights-of-way. Currently, SCWA provides recycled water in the SSA as part of a pilot project in the Laguna West, Lakeside, and Laguna Stonelake service areas (Phase 1 Area) that are located in the western portion of the Laguna subarea. Recycled water has historically been a small portion of the supply for Zone 40, as shown on an annual basis on Figure 4-2 and a monthly basis on Figure 4-3.

Recycled water supply availability will increase in the future when SRCSD completes the Echo Water Project in 2023. Recycled water use would increase to a total of 3,300 ac-ft/yr when the Phase 2 recycled water system is completed in the East Franklin and Laguna Ridge areas in the SSA (Phase 2 Area). SCWA is not planning on the addition of purple pipe for recycled water beyond what is planned as part of its long term recycled water strategy. Recycled water supply is assumed to be available at 100 percent of full supply in wet/average, drier, and driest years.

There is an emerging trend in California to use recycled water as an indirect source of potable water, known as indirect potable reuse. There are a limited number of water suppliers in California that are introducing recycled water into their potable water supplies through groundwater recharge. The City of San Diego is implementing a program that will result in augmenting one of their surface water supply reservoirs with recycled water. Studies are ongoing to develop requirements for direct potable reuse of recycled water. The attractiveness of these approaches is that the enormous costs of recycled water pipeline distribution systems can be avoided. SCWA developed a long term recycled water strategy that was approved by the Board that includes possible consideration of these options.

4.5 Water Supply Portfolio

The various water supplies available to SCWA combine to form Zone 40's water supply portfolio. SCWA has implemented a conjunctive use program within Zone 40 that optimizes the use of groundwater and surface water based on hydrologic conditions.

Historically, SCWA relied primarily on groundwater to provide water service to its customers. Existing groundwater pumping capacity plus a relatively small amount of surface water through the Franklin Intertie had been sufficient to meet system wide water demands. With the completion the Freeport project and the Vineyard SWTP, SCWA has been able to more fully implement a conjunctive use program that results in a variation of the mix of supplies based on the water year type. Conjunctively using surface water and groundwater allows SCWA to reduce surface water diversions and increase groundwater use in dry years. In wet and average years SCWA can increase surface water use and decrease groundwater use, thereby not exceeding the long term sustainable yield of the underlying groundwater basin.

Table 4-2 presents SCWA's unconstrained water supply portfolio for wet/average, drier, and driest years. Table 4-2 also presents the long-term average use on an annual basis of each supply source assuming that all of the available water supplies are fully used for each climate year type. SCWA would have to construct additional supply, treatment, and conveyance facilities to fully access the available water supplies presented in Table 4-2. Figure 4-5 illustrates the Zone 40 available water supply in each year type assuming that supply facilities with adequate capacities are available. The long-term average supply availability may change if the frequency of occurrence of different water year types changes in the future, such as due to the impacts of climate change. Section 5 presents the annual supplies that are available with the constraint of the capacity of the facilities and the projected use of the supplies.

Table 4-2. Zone 40 Water Supply Portfolio, ac-ft/yra								
Supply Source Wet/Average Year Drier Year Driest Year Long-Term Aver								
Surface water ^c	89,300	43,350	32,100	71,858				
Groundwaterd	34,900	64,900	71,900	46,260				
Recycled water	3,300	3,300	3,300	3,300				
Total	127,500	111,550	107,300	121,418				

- a. These water supply values are not constrained by water supply facility capacities. SCWA would have to construct additional supply, treatment, and conveyance facilities to fully access the available water supplies presented in this table.
- b. Based on full use of all supplies for each water year type. The frequency of occurrence for the wet/average, drier, and driest years assumed to be 64 percent, 28 percent, 8 percent of the years respectively, based on an analysis of a 70-year hydrologic period (SCWA, 2006, Pg. 7-3).
- c. The surface water drier and driest year supplies could be less if the prior 3-year historical CVP use is less than the CVP contract amount. See Table 4-1 and text. The 25 percent surface water supply allocation from Bureau of Reclamation in 2015 is not reflected in the driest year value.
- d. Includes the 8,900 ac-ft/yr remediated groundwater supply. Groundwater supply amounts are the projected annual groundwater use at buildout presented in Section 5.

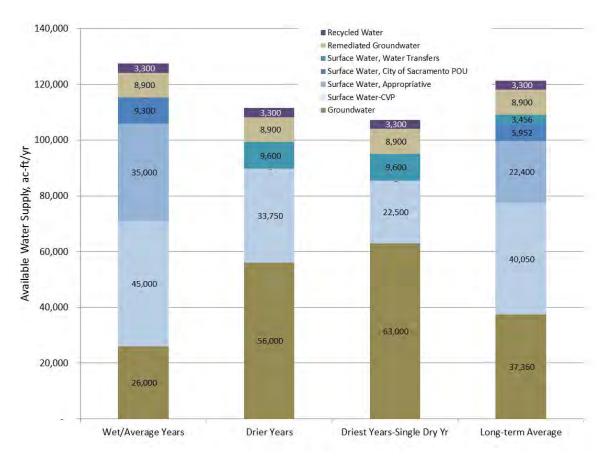

Figure 4-5. Available Water Supplies

Section 5

Water Supply Capacity Approach

This section describes the approach to quantify the amount of supply capacity that would be needed to meet Zone 40 demands through buildout. This information is needed to properly size the future water supply facilities. The capacity of the current system to supply current water demands is evaluated. The approach to evaluate storage requirements is presented.

5.1 Maximum Day Demand Supply Capacity and Use

Zone 40 needs enough water supply capacity to meet the projected future maximum day demand for both wet and dry climate years. The maximum day demand condition is important because the water supply facilities are sized to meet and exceed that condition. The planned future water supply capacity is based on the construction of new groundwater, surface water, and recycled water supply and conveyance facilities that are described in subsequent sections of this report for each of the scenarios. The maximum day demand is estimated using a maximum day demand peaking factor of 2.0.

Both wet year and dry year scenarios are considered in quantifying the needed water supply capacity. The total capacity of all water supply facilities must significantly exceed the maximum day demand because of the requirements of the conjunctive use program. The future water supply capacity is developed to meet the projected maximum day demands while allowing SCWA to vary the mix of supplies based on water year type. The water supply capacity is developed with the approach to increase the use of surface water in wet/average years and groundwater in dry years (conjunctive use program). The supply capacities include the supply for the Elk Grove and Rio del Oro wholesale areas as well as the Zone 40 retail area.

The remediated groundwater is categorized as part of the surface water supply capacity and use since it is conveyed through the surface water facilities. The groundwater capacity and use only reflects groundwater produced from wells owned and operated by SCWA.

The timing of the supply capacities is developed based on three phases. The period to December 2025 is considered Phase 1, January 2026 to December 2035 is considered Phase 2, and Phase 3 is the period from January 2036 through buildout.

Figure 5-1 presents a comparison of the total capacity of the existing water supply facilities to the 2013 maximum day demand for each of the service areas. The 2013 demand data is used because it is not influenced by the drought, making it higher than current demands. The detailed supply capacity to demand tables for each service area are presented in Appendix B for 2013. As shown on Figure 5-1, the capacities of all of the existing water supply facilities exceed the maximum day demands for each service area. All three of the service areas currently have adequate groundwater supply capacity to meet their current maximum day demand without the use of surface water. There is enough surface water supply capacity in the CSA to meet the CSA's current maximum day demand without the use of groundwater. The NSA and the SSA currently have a more limited supply of surface water that cannot fully supply the maximum day demand.

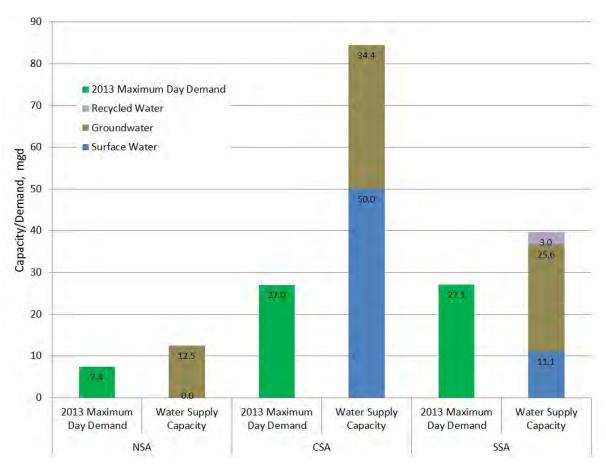

Figure 5-1. 2013 Maximum day demand and supply capacity by service area

5.1.1 North Service Area

The NSA is currently supplied primarily by surface water from the existing Vineyard SWTP conveyed using the newly constructed Phase A NSA pipeline. The existing groundwater supply and treatment facilities in the NSA have the capacity to meet the maximum day demand. The Anatolia GWTP and Mather Housing GWTP are the major groundwater facilities. The Mercantile interconnection with Golden State Water Company is only used for emergency purposes.

5.1.2 Central Service Area

The CSA is currently supplied by groundwater from existing groundwater treatment plants and some direct feed wells and surface water from the Vineyard SWTP. The existing groundwater facilities have the capacity to supply all of the current maximum day demand. Similarly, the Vineyard SWTP's current 50 mgd capacity is more than adequate to supply all of the CSA's current maximum day demand.

Water supplies produced in the CSA can be delivered to the SSA through the three connections between the CSA and SSA. These connections are located along Highway 99 at Sheldon Road, Bond Road, and Grant Line Road. The total capacity of these connections is approximately 30 mgd.

5.1.3 South Service Area

The SSA is currently supplied by surface water from the Franklin intertie and the Vineyard SWTP, groundwater from three existing groundwater treatment plants and some direct feed wells, and a small amount of recycled water. The existing groundwater facilities in the SSA have the capacity to supply all of the current maximum day demand.

As described previously, the three existing connections between the CSA and SSA can be used to supply surface water or groundwater to the SSA from the CSA.

5.2 Annual Water Supply Capacity and Use

The available supply capacity and use of supply are developed for each scenario on an annual basis because the values are directly useable for the development of water supply assessments and urban water management plans. The available water supply amounts that are described in Section 4 represent the full amount of available supply assuming there are no facility capacity constraints. The supply capacities and use of supplies are constrained by the supply and conveyance facility capacities.

The annual supply capacity and use are determined using the maximum day supply capacity and use. The proportional capacity and use of each water supply type on an annual basis is assumed to be the same as the mix of supplies on the day of maximum day. The annual supply capacity and use of supply is determined by assuming that the annual average day capacity or use is 50 percent of the capacity or use on the day of maximum demand. For example, a water supply capacity of 50 mgd equates to an annual average day capacity of 25 mgd or an annual capacity of 28,000 ac-ft/yr.

The actual annual use of supplies could differ from the values presented in this section if SCWA took an operational approach that would result in the annual mix of supplies being different than the mix of supplies used during the day of maximum demand. For example, in a dry year groundwater could be used to meet all of the demands in the winter, spring, and fall months. This would result in less surface water and more groundwater being used annually than what is presented in this section. Similarly, in a wet year surface water could be used to meet all demands in the winter, spring, and fall months. This would result in less groundwater and more surface water being used annually than what is presented in this section.

The remediated groundwater is included in the annual surface water values since it is conveyed through the surface water facilities. The annual groundwater amounts are only for the wells owned and operated by SCWA and exclude the groundwater remediation extraction.

One of the climate year types is expressed as multiple dry years to be consistent with the climate year types used for water supply assessments and urban water management plans. The multiple dry three year period is assumed to mimic the hydrology of 1989, 1990, and 1991 (SCWA, 2011). The CVP allocations for those three years were 100, 75, and 50 percent, respectively. The dry year CVP allocations are based on a percentage of the last three year historical use.

5.3 Storage and Pumping Station Capacity Evaluation Approach

This section presents the approach used to conduct the storage analysis that establishes the sizing and timing of future water storage facilities. Since it is not cost effective to size groundwater and surface water supply facilities to supply demands that occur above the maximum day demand rate, water storage is used to supply these short term demands. The short term demands that can last for a few hours are the peak hour demands and fire flow demands.

Since Zone 40 does not have high enough terrain to locate tanks that can provide adequate pressure with gravity flow, ground level tanks must be used in conjunction with pump stations to pump the stored water into the distribution system. The use of elevated storage tanks is typically not cost effective in the larger storage volumes required for Zone 40. The storage evaluation has two elements, consisting of the storage volume and pump station capacity.

5.3.1 Storage Volume

The required minimum storage volume is the sum of the following three components:

Equalization Storage. Water is provided for equalization storage to meet the increment of peak demands that exceed the maximum day demand. Equalization storage is assumed to be 20 percent of the maximum day demand.

Emergency Storage. Volume is also required for emergency supplies in the event normal supplies are not available. Emergency storage is assumed to be 1/3 of the average day demand. Many water agencies have criteria to provide greater amounts of emergency storage such as one average day demand. However, since SCWA can utilize the underlying groundwater basin to provide additional volume, the sizing assumption is reasonable.

Fire Flow Storage. Water is stored to provide fire flow. Fire flow storage is assumed as the volume for two fires for each service area, with each fire requiring 3,000 gpm for 3 hours. SCWA also has storage provided by the groundwater basin that can provide a large volume of water. Some building types can have fire flow requirements that are higher. The assumption of having fire storage for two simultaneous fires in each service area provides enough storage for one larger fire flow rate or longer duration fire flow.

5.3.2 Pump Station Capacity

Pump stations must have the capacity to supply peak hour demand. The peak hour demand is estimated using a peak hour factor of 2.0 applied to the maximum day demand. There are two situations in Zone 40 that govern the sizing of the pump stations that are used with storage tanks. A pump station that pumps from a standalone storage tank can use its entire pumping capacity to draw water from storage. A pump station that pumps from a tank that is supplied by a GWTP or a SWTP must be sized large enough to be able to pump the supply from both the GWTP and from the storage facility. Only the portion of the pump station capacity that is larger than the GWTP or SWTP capacity is considered to be able to utilize the stored water. Both situations are considered in the storage pump station evaluation.

In situations where a GWTP or SWTP has surplus maximum day capacity, some of that surplus could be used to help supply demands that are greater than the average rate on the maximum demand day. In these types of situations, the required pump station capacity to meet peak hour demand would be less than presented in this analysis.

Section 6

Water System Facilities and Capital Improvement Plan Approach

This section describes the approach used to identify the needed water system facilities and develop the resulting CIP.

6.1 Needed Water System Facilities

The water supply facilities are sized to provide the maximum day surface water and groundwater supply capacities for each scenario (e.g. dry year or wet year and Baseline or Plan Area). The storage tank and pumping station facilities are defined based on the storage evaluation developed for each scenario. The water supply, storage, pump station, and pipeline improvements have been identified by SCWA staff and are defined based on water system modeling performed by SCWA staff that is documented in the WSIP.

The sizing and timing of the water supply facilities are developed based on several general conjunctive use guidelines, as described below.

- The groundwater supply should be able to provide enough maximum day supply in dry years to
 mitigate the reductions in surface water supply that could occur. The guideline is to be able to
 provide enough groundwater supply assuming a surface water supply that is reduced during the
 day of maximum demand in dry years by up to approximately 50 percent of its maximum day use
 in wet/average years.
- 2. The surface water supply should be able to supply a significant portion of the maximum day demand in a wet/average year while only using a portion of the groundwater supply capacity. The guideline is to provide enough surface water supply capacity to be able to supply approximately 50 percent or more of the maximum day demand.

6.2 Capital Improvement Plan

The CIP is developed based upon the water facilities identified in Section 6.1. The CIP is presented in three phases as follows:

- Phase 1. 2020 to 2025
- Phase 2, 2026 to 2035
- Phase 3. 2036 to buildout

The CIP projects are categorized as surface water projects, groundwater projects, pipeline projects, and storage projects. Each of the planned facilities for each scenario (e.g. dry year or wet year) is identified by a CIP project identification number. Groundwater treatment projects are identified as GWTP followed by a number. Groundwater well projects are identified as GW. Surface water projects are identified as SW, storage projects as S, and pipeline projects as P.

The projects presented in the CIP are limited to projects that expand the water supply capacity and the conveyance of water supplies to future customers. Not included in the CIP are the following types of projects and items:

- Projects that rehabilitate or replace existing water system facilities.
- Projects that correct existing system deficiencies, such as areas of inadequate pressure or fire flow.
- Land acquisition.
- Projects that provide for groundwater treatment for constituents other than iron and manganese. For example, projects needed to treat constituents that are found to a limited extent in the Central Basin such as Chromium VI. Arsenic, and Radon are not included.
- Projects that would plan and implement aquifer storage and recovery (ASR).
- Projects that would plan and implement an expanded recycled water supply beyond the project RW-1. For example, not included are projects that consist of indirect potable reuse (IPR) or direct potable reuse (DPR) of treated wastewater.
- Special fees or payments.
- Water system connection fees, such as for future interties with other water agencies.

The CIP projects included in each phase are presented in Section 7.

6.3 Basis of Cost Estimates

The cost estimates represent conceptual estimates of the capital costs to construct the water system facilities. Costs should be refined from this conceptual phase as the projects are better defined and proceed into the pre-design and design phases. The cost estimates represent 2014 dollars. Capital cost estimate tables are presented for most of the CIP projects in Appendix D with several exceptions. SCWA provided the cost estimates for the Phase B NSA Project (S-1). The Vineyard SWTP expansion project (SW-1) and recycled water project (RW-1) do not have individual cost estimate tables developed.

Capital costs represent the construction and other costs necessary to get a project completed. Construction costs cover the material, labor, and services necessary to build the identified project. Changes during the design of the project, in the cost of materials, labor, and equipment, and in the bidding environment will cause changes in the estimated cost.

The contingency cost item addresses the uncertainties that are associated with the preliminary sizing of projects. Factors such as unexpected construction conditions, the need for unforeseen construction items, and variations in quantities are some of the items that can increase project cost. An allowance of 25 percent of the construction cost is included to cover such contingencies for the groundwater, surface water, and storage projects.

The engineering, administrative, and legal cost item covers engineering services and items such as legal fees, administrative costs that are typically associated with a project. It is estimated that these costs would be 25 percent of the total of the construction cost plus contingency.

The environmental and permitting cost item is intended to cover services necessary to meet the requirements of the California Environmental Quality Act and services and fees associated with obtaining the necessary permits that would be required. It is estimated that these costs would be 10 percent of the total of the construction cost plus contingency.

The cost estimates for the Phase 1 pipeline projects, which are developer projects, are developed with a different approach. The cost estimates for the developer projects represent the amount that

SCWA would pay a developer for a project and do not necessarily represent the total cost of a project. The cost estimates for the pipeline projects are based on the unit costs presented in Schedule C that was issued by SCWA on April 9, 2014. The pipeline projects are characterized as being either in undeveloped areas or under existing pavement to utilize the appropriate Schedule C unit pipeline cost. The Schedule C unit costs are values that have been escalated from unit costs that were developed in 2007 for the development of the Ordinance 18 Schedule C Unit Prices for Zone 40 Credits. The cost estimates for the developer projects include 15 percent for contingency, 8 percent for engineering, and 10 percent for the Construction Management and Inspection Division (CMID).

It is assumed that all future groundwater supply facilities would require groundwater treatment for iron and manganese. The groundwater treatment plant projects each include wells, pipelines from the wells to the treatment plant, treatment facility, storage reservoir, pumping station, and pipeline conveyance to the water distribution system. It is assumed that treatment facilities will not be required for the existing direct feed wells.

The cost for the expansion of the Vineyard SWTP (SW-1) is based on a unit cost of \$4 million per mgd capacity. The cost estimate for the recycled water project (RW-1) is assumed to be \$20 million, but no recycled water facility project description has been developed for this study. As a comparison, the 2005 WSMP estimated the cost of the recycled water facilities to be \$15 million and the 2006 WSIP presented a cost of \$11.6 million.

This page intentionally left blank.

Section 7

Baseline

This section describes the demographics, water demands, water supplies, and needed water system improvements for the Baseline scenario. The Baseline scenario includes the existing approved Zone 40 and the NewBridge, West Jackson, and Jackson Township growth areas.

7.1 Water Demands

This section describes the future land use, demographics, and demand projections for the Baseline scenario.

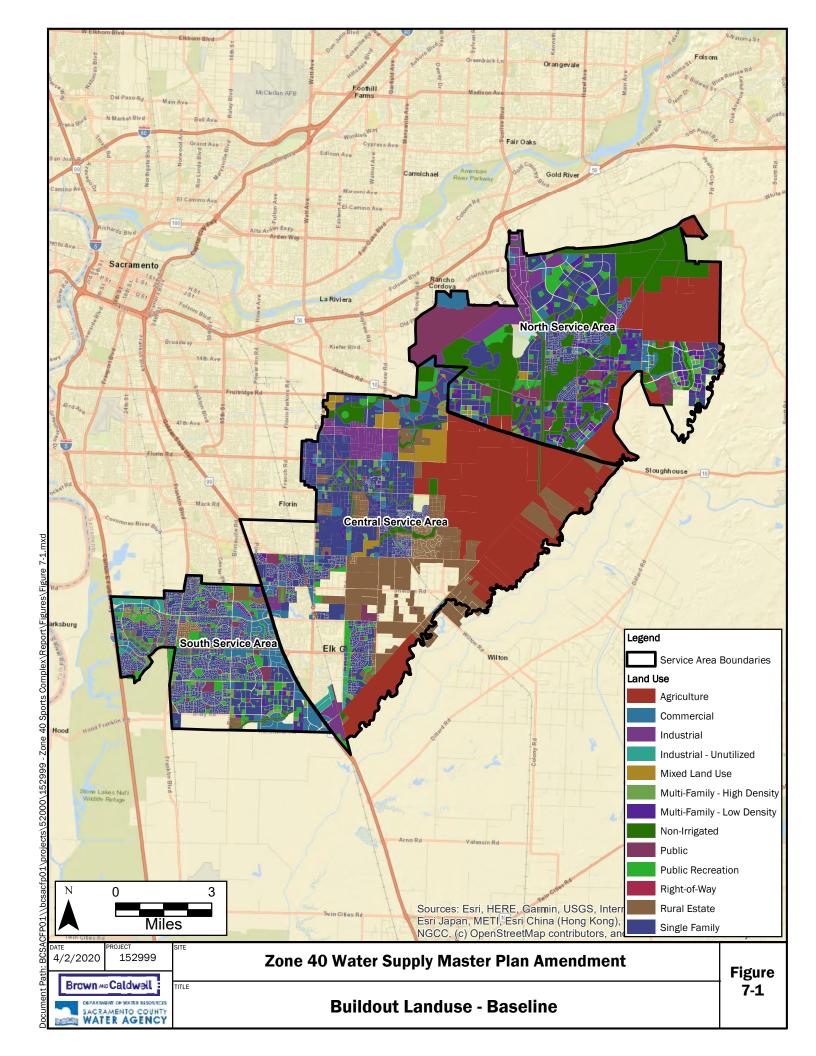

7.1.1 Buildout Demographics

The buildout developed land use acreages by land use category for the Baseline Scenario are summarized in Table 7-1. The acreages presented in Table 7-1 are net acres for 2010 and gross acres for the study area at buildout. The buildout land use for the study area is illustrated on Figure 7-1.

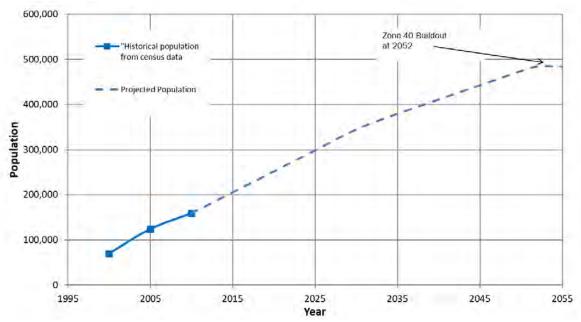

Table 7-1. 2010 and Buildout Area By Land Use - Baseline						
Land Use Category	2010 Developed Area, Net Acres	Buildout Area, Gross Acres				
Rural estate	1,380	6,870				
Single family	6,970	18,140				
Multi-family - low density	220	3,750				
Multi-family - high density	390	1,310				
Commercial	1,520	4,330				
Industrial	1,110	3,470				
Industrial-unutilized	340	580				
Public	920	2,120				
Public recreation	1,270	4,820				
Mixed land use	20	1,230				
Right-of-way	70	580				
Subtotal, municipal water supply land area	14,210	47,200				
Self-supported/supplied by others	-	870				
Non-irrigated	500	9,800				
Agricultural	-	11,620				
Total	14,710	69,490				

Note: Elk Grove wholesale area is not included in the 2010 developed area acreage and is included in the buildout acreage because it was not available.

The historical and projected population for existing approved Zone 40 is shown on Figure 7-2. The projected DUs, population, and connections at buildout by land use category are presented in Table 7-2. Population per DU and per connection, DUs per connection, and connections per acre by land use category are also shown in this table. The number of people per connection projected at buildout is significantly higher than the 2010 value because of the proportionally large increase in multifamily land use area compared to single family land use area from 2010 to buildout. A larger proportion of the residential dwelling units and connections will be multifamily at buildout compared to 2010, which will result in a higher number of people per connection.

Elk Grove wholesale population is included. 2010 Elk Grove wholesale population is estimated to equal 10,144 people based on 3,210 Elk Grove wholesale connections and 3.16 people per connection in 2010. The historical population has not been updated for this WSMP amendment.

Figure 7-2. Historical and projected population in zone 40 - baseline

Table 7-2. Buildout Dwelling Units, Population, and Connections by Land Use Category - Baseline								
Land Use Category	Dwelling Units	Population	Connections	Population Dwelling Unit	Population Connection	Dwelling Units Connection	Connections Acre	
Rural estate	3,300	11,000	3,300	3.3	3.3	1.0	0.5	
Single family	87,100	287,500	87,100	3.3	3.3	1.0	4.8	
Multi-family - low density	41,800	115,000	4,200	2.8	27.4	10.0	1.1	
Multi-family - high density	27,700	70,700	1,800	2.6	39.3	15.0	1.4	
Commercial			1,900				0.4	
Industrial			1,400				0.4	
Industrial-unutilized							-	
Public			200				0.1	
Public recreation			4,100				0.9	
Mixed land use			500				0.4	
Right-of-way			700				1.2	
Self-supported/ supplied by others			-					
Non-irrigated			-					
Agricultural			-					
Total	159,900	484,200	105,200	3.0	4.6	1.5	1.5	

a. Totals are rounded to the 100's place.

The baseline scenario DUs, population, and connections by service area are shown in Table 7-3. The projected buildout number of DUs and population for the NSA, CSA, and SSA are very similar; however the numbers of connections in the NSA are significantly less than the CSA and SSA. This is because there is a greater number of multi-family DUs in the NSA than the CSA and SSA. Since there are several multi-family dwelling units per connection, a lower number of connections is projected in the NSA to serve the similar number of dwelling units.

Table 7-3. 2010, 2019, and Buildout Dwelling Units, Population, and Connections by Service Area - Baseline									
	2010			2019		Buildout			
Service Area	Dwelling Units	Population	Connections	Connections	Dwelling Units	Population	Connections		
NSA	4,000	11,700	4,600		54,300	159,600	28,800		
CSA	17,400	56,600	15,600		54,300	166,200	38,300		
SSA	30,600	91,300	28,900		51,300	158,400	38,100		
Total Zone 40	52,000	159,600	49,100	55,200	159,900	484,200	105,200		

Note: 2010 dwelling units, population, and connections in Elk Grove wholesale area are estimated and included in the CSA values. Elk Grove wholesale area service connections in 2010 are estimated to be 3,200 connections and the DUs are estimated to be 3,500 based on a 1.1 DU per connection factor. The population is estimated to equal 10,144 people. 2019 connections are per data provided by SCWA.

Table 7-4. Projected Connections in 5-Year Increments - Baseline									
Service area	2020	2025	2030	2035	2040	2045	2050	Buildout (2052)	
NSA	7,500	10,000	12,500	16,100	19,800	23,600	27,300	28,800	
CSA	18,400	20,900	23,400	27,000	30,800	34,500	38,300	38,300	
SSA	32,800	35,300	37,800	38,100	38,100	38,100	38,100	38,100	
Total	58,800	66,300	73,800	81,300	88,800	96,300	103,800	105,200	

Note: 55,200 connections in 2019. The projection of future connections has not been revised for this WSMP amendment.

Table 7-4 shows the projected number of connections by service area in five-year increments through 2050 and at buildout. The projected number of connections through buildout for each of the growth scenarios is illustrated on Figure 7-4. The projection number of connections in Table 7-4 and Figure 7-3 has not been updated for this WSMP amendment. As shown in Figure 7-3, the actual 2019 number of connections is tracking at low growth scenario. If this trend continues, the buildout year would be after 2055.

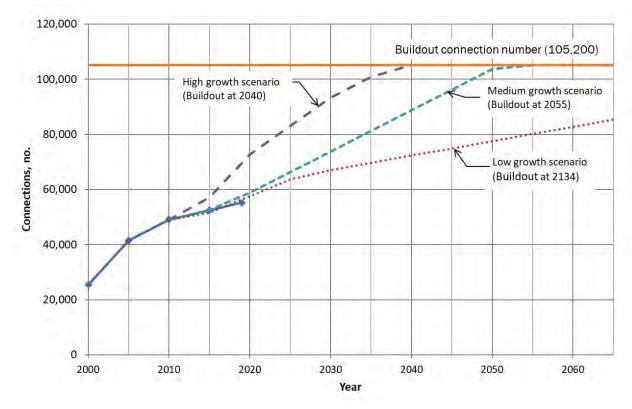

Figure 7-3. Historical and projected Zone 40 connections at High, Medium, and Low growth rates - baseline

Note: The projection of future connections has not been revised for this WSMP amendment.

7.1.2 Buildout Water Demands

This section presents the buildout water demand for the Baseline scenario. The buildout water demand by land use category for the Baseline scenario is shown in Table 7-5. The recycled water demand in the SSA is included in the demand projections in Table 7-5 to provide the total water

demand for this scenario. The buildout water demand for the baseline scenario has not been updated for this amendment. As described in the following Section 7.1.3, the actual 2019 Zone 40 water use was significantly less than the 2020 demand projection presented in Table 7-6. The lower 2019 demand may be partially due to changed water use characteristics by customers as a consequence of the severe 204 to 2015 drought. Therefore, it might be possible that an updated evaluation of the projected Zone 40 demand at buildout may result in a smaller buildout demand for this scenario.

Table 7-5. Buildout Water Demand by Land Use Category - Baseline						
Land Use Category	Water Demand, ac-ft/yr					
Rural estate	9,400					
Single family	38,600					
Multi-family - low density	9,200					
Multi-family - high density	4,400					
Commercial	8,700					
Industrial	7,000					
Public	1,700					
Public recreation	13,500					
Mixed land use	2,600					
Right-of-way	100					
Subtotal (land use with water demand)	95,300					
Water system losses (7.5% of water sales)	7,100					
Self-supplied/supported by others	0					
Industrial-unutilized	0					
Non-irrigated	0					
Agricultural	0					
Total production	102,400					

7.1.3 Water Demand Growth Projection

The projected water demands by service area for the medium growth scenario are shown in Table 7-6 and illustrated on Figure 7-4. The water demand projection has not been revised for this WSMP amendment. The 2019 water demand was 31,330 ac-ft/yr, which is 31 percent lower than the demand projected for 2020. As indicated this 2019 water demand and by the actual number of connections in 2019 presented on Figure 7-3, the projected water demands for the medium growth scenario in Table 7-6 and Figure 7-4 may overstate the projected demands.

Table 7-6. Projected Water Demand in 5-Year Increments - Baseline, ac-ft/yr										
Service Area	2020	2025	2030	2035	2040	2045	2050	Buildout (2052)		
NSA	7,300	10,100	13,100	17,500	22,400	27,500	32,800	34,900		
CSA	18,400	21,200	24,100	28,100	32,400	36,800	41,300	41,400		
SSA	19,700	22,600	25,600	26,100	26,100	26,100	26,100	26,100		
Total	45,500	53,900	62,800	71,800	80,900	90,400	100,300	102,400		

Note: The water demand in 2019 was 31,330 ac-ft/yr. The water demand projection has not been revised for this WSMP amendment.

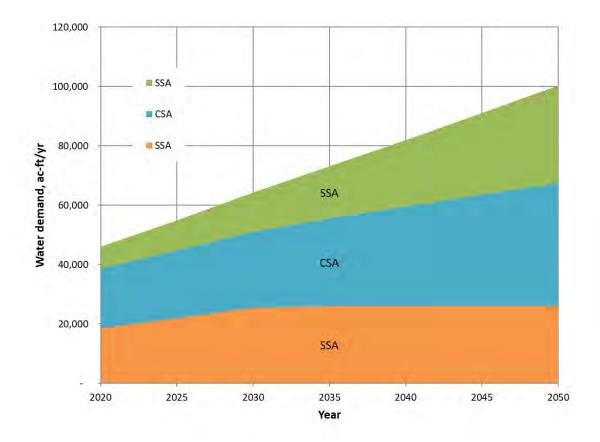

Figure 7-4. Water demand projection - baseline

Note: The water demand in 2019 was 31,330 ac-ft/yr. The water demand projection has not been revised for this WSMP amendment.

7.2 Water Supply Capacity

This section quantifies the amount of supply capacity that would be needed to meet demands through buildout. The supply capacity and the use of the supply are presented on both a maximum day basis and an annual basis.

7.2.1 Maximum Day Demand Supply Capacity and Use

This section compares the projected maximum day demand to supply capacity for each of the three service areas through buildout. The maximum day demand to supply capacity comparison tables for each of the three service areas are presented in Appendix B. The future supply capacity is based on the proposed supply and conveyance facilities that are presented in Section 7.3. The maximum day use of each type of supply is quantified for the wet/average years and dry years.

7.2.1.1 North Service Area

Surface water supply from the existing Vineyard SWTP is being conveyed to the NSA to supplement the current groundwater supply. The construction of the Phase B NSA Project (S-1) will allow for more of the Vineyard SWTP's existing capacity to be used to supply the NSA. It is assumed that 65 percent of the Vineyard SWTP would be used to supply the NSA. The Mather wells are used below their capacities in dry years since SCWA operational staff prefer to minimize their use due to the possible impact to nearby contamination plumes.

7.2.1.2 Central Service Area

Once several projects are constructed, including the Phase B NSA Project (S-1), more of the Vineyard SWTP's existing capacity will be used to supply the NSA. The future West Jackson GWTP will be used to supply the CSA, although it will be connected to the transmission system such that it could also provide supply to the NSA.

7.2.1.3 South Service Area

New groundwater supply capacity would be needed during Phase 1. Additional groundwater supply capacity would be added in Phases 2 and 3. No new surface water supply capacity is specifically planned for the SSA, although the planned Phase 3 expansion of the Vineyard SWTP would provide some additional surface water. The proposed GWTPs for Phase 3 would provide a maximum day groundwater supply capacity that exceeds the SSA's projected buildout maximum day demand. These Phase 3 GWTPs could be used to provide dry year groundwater supply to other areas or groundwater storage, or function as additional backup facilities.

7.2.1.4 Zone 40 Summary

Table 7-7 and Figure 7-5 present the maximum day demand and supply capacity comparison for Zone 40 from 2013 through buildout. The maximum day use of each type of supply is quantified for the wet/average years and dry years. As can be seen in Table 7-7 and consistent with the established conjunctive use program, the total supply capacity exceeds the maximum day demand for each phase, but neither the groundwater nor surface water supply capacity alone can meet the maximum day demand.

As shown in Table 7-7, Zone 40 will utilize a varying mixture of groundwater and surface water supplies on the maximum demand day based on whether it is a wet/average year or a dry year. The ability to practice conjunctive use by maximizing the use of surface water in wet and average years and minimizing the use of surface water in dry years is limited by the available surface water and groundwater supply capacities and to some extent by distribution system constraints. Several observations are made regarding the maximum day supply capacity and use that pertains to all three phases:

- 1. In dry years, there is sufficient groundwater capacity to be able to significantly reduce the amount of surface water use on the maximum day compared to wet/average years.
- 2. In dry years, most of the groundwater capacity will be utilized on the maximum demand day.

- 3. In wet years, there is sufficient surface water capacity to be able to supply over half of the maximum day demand.
- 4. In wet years, up to half of the groundwater capacity will be used to help supply the maximum day demand.

Table 7-7 Maximum Day Demand to Supply Comparison for Zone 40 - Baseline, mgd										
		Pha	se 1		Pha	se 2			Phase	:3
Zone 40	2013	2015	2020	2025	2030	2035	2040	2045	2050	Buildout (2052)
Maximum day demand										
Zone 40 total	61.5	69.2	81.2	96.3	112.2	128.1	144.4	161.4	179.0	183.0

Surface water	0.0	1.9	17.7	24.8	32.1	32.3	40.9	50.0	65.0	69.0
Recycled water	3.0	3.0	3.0	3.0	3.0	3.0	3.0	3.0	5.9	5.9
Total	61.5	69.2	81.2	96.3	112.2	128.1	144.4	161.4	179.0	183.0

Note: The projected maximum day water demand has not been revised for this WSMP amendment.

- a. Groundwater supply decrease in 2020 due to Anatolia GWTP removed from service.
- b. Reduction in existing capacity and added future surface water supply capacity in 2020 and 2025 because planned delivery to NSA from existing Vineyard SWTP accounted as future supply capacity as requested by SCWA staff.

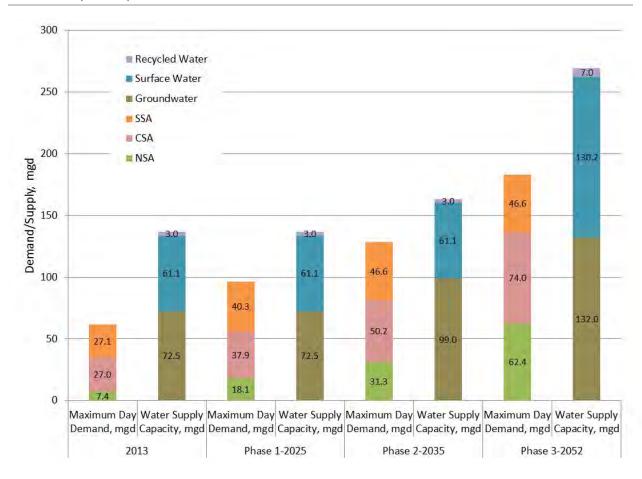

Figure 7-5. Maximum day demand to supply capacity comparison by phase - baseline

Figure 7-6 presents the maximum day use of the water supplies by type for wet/average years and dry years for 2013, Phase 1, Phase 2, and Phase 3.

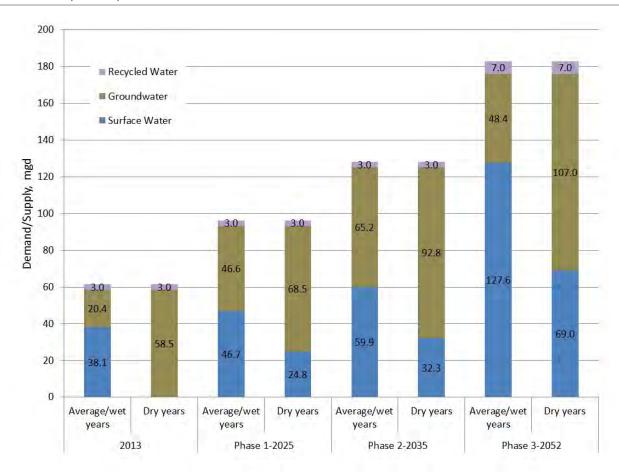

Figure 7-6. Maximum day use of water supplies by phase and climate year type - baseline

7.2.2 Annual Water Supply

Table 7-8 presents the annual supply to demand comparison for a normal climate year. Table 7-9 presents the annual supply to demand comparison for a single dry year and Table 7-10 presents the comparison for a multiple dry year. The presented supply values are the supplies available to Zone 40 assuming there are no facility supply capacity constraints. The facility improvements needed to expand existing supply capacity are presented in Section 7.3. Projections of the use of each supply source that consider supply facility capacity constraints for each service area for normal and dry years are presented in Appendix B. Figure 7-7 presents the projected use of water supplies by phase and climate year type.

As can be seen in Tables 7-8, 7-9, and 7-10, as well as in Appendix B, the total water supply is greater than the projected demands. This analysis verifies the sufficiency of the water supply for the Baseline scenario.

Table 7	Table 7-8. Supply and Demand Comparison-Normal Year, ac-ft/yr – Baseline												
	2015	2020	2025	2030	2035	2040	2045	2050	Buildout (2052)				
Supplies, no facility constraints													
US Bureau of Reclamation-CVP supply	45,000	45,000	45,000	45,000	45,000	45,000	45,000	45,000	45,000

Note: The water demand projection and the third year CVP supply allocation have not been revised for this WSMP amendment.

a. Only 35,000 ac-ft/yr assumed to be available without the construction of seasonal storage, as described in Section 4.2.2.

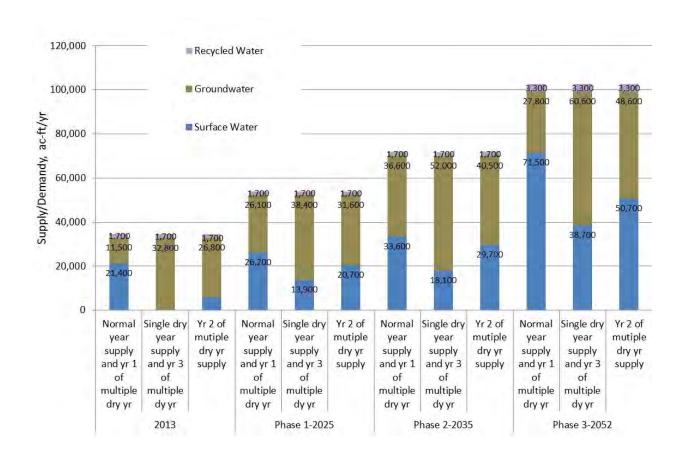

Figure 7-7. Zone 40 Annual use of water supplies by phase and climate year type

7.2.3 Storage and Pumping Station Capacity Evaluation

Table 7-11 and 7-12 presents a summary comparison of the planned to required storage volume and pumping station capacities for this scenario. As shown in Tables 7-11 and 7-12, the planned storage facilities provide more than the required storage volumes and pump station capacities. The detailed storage evaluation tables for each pressure zone are presented in Appendix B.

Table 7-11. Z	one 40	Storage Capacity Evalu	uation Summary- Basel	ine
	2013	Phase 1 (2020-2025)	Phase 2 (2026-2035)	Phase 3 (2036-2052)

7.3 Water System Facilities and Capital Improvement Program

This section describes the water system facilities needed to supply the Cumulative scenario, develops the costs, and presents the CIP for Phases 1, 2, and 3.

7.3.1 Needed Water System Facilities

The water system facilities needed to serve the Baseline scenario through buildout are defined in this section.

7.3.1.1 Phase 1 (2020 to 2025)

The water system facilities needed to serve the Phase 1 demands are described for the NSA, CSA, and SSA.

North Service Area

As water demand continues to grow in the NSA, new water supply capacity will be needed to keep up with the demand growth. The Phase A NSA Pipeline was recently constructed by SCWA in order to increase the surface water use in Zone 40 as part of the conjunctive use program. The existing Vineyard SWTP has additional capacity beyond what is needed to supply the CSA's current maximum

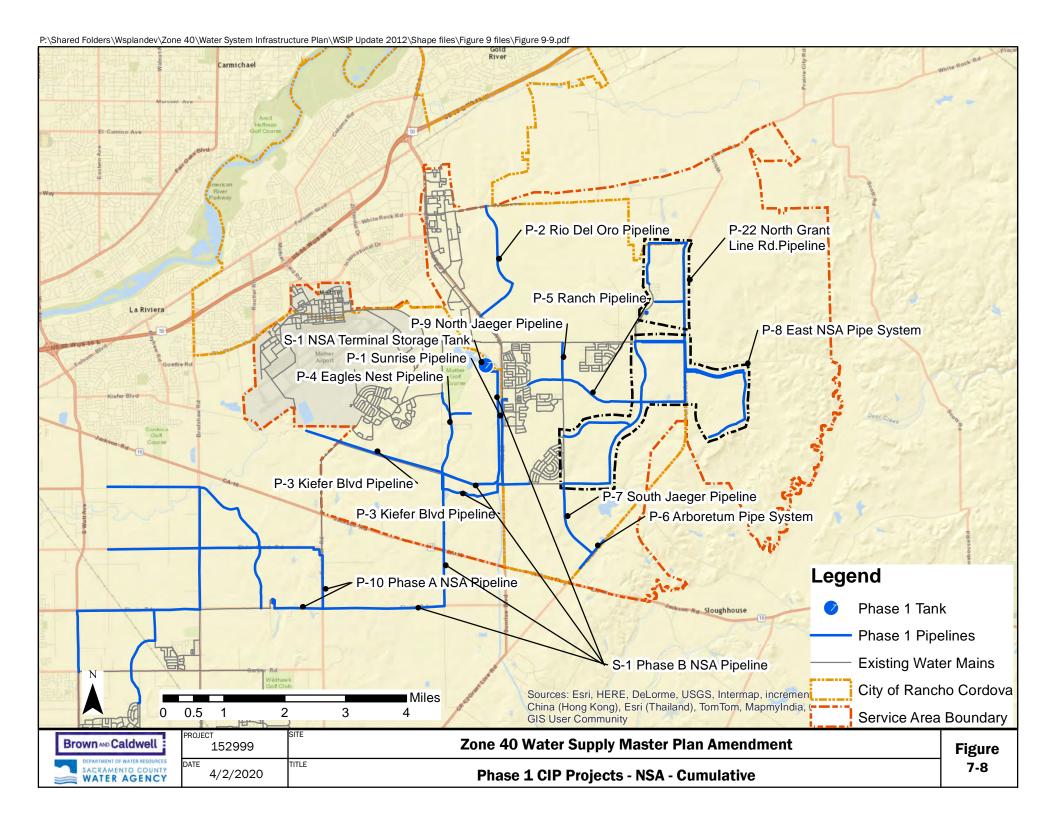

day demand. The Phase A NSA Pipeline has the capacity to deliver up to 11,000 gpm (or 15.8 MGD) to the NSA.

Once the demand for surface water in the NSA exceeds the capacity of the Phase A NSA Pipeline, a new pipeline would be constructed. This new pipeline would be part of the Phase B NSA Project (S-1), which would also include the NSA terminal storage and pumping facility. The planning and project initiation is expected to begin in Phase 1, with project completion currently anticipated in 2029 in Phase 2. The Phase B NSA Project (S-1) would provide for conveyance of surface water supply from the Vineyard SWTP to the NSA terminal storage and pumping facility from which the surface water supply would be distributed to the NSA, including peak hour and fire flow needs. The Phase B NSA Pipeline (54-inch in diameter) starts from Florin Road at Excelsior Road, extending east on Florin Road and then turning north in Eagles Nest Road, Kiefer Road, and the west bank of Folsom South Canal, and ultimately ending at the NSA terminal tanks (10 MG) located in Mather South. There may be approaches to optimize the Phase B NSA Project (S-1) by not having all of the Vineyard SWTP surface water supply conveyed to the NSA terminal storage and pumping facility. For example, additional storage facilities could be located in the southern portions of the NSA to be supplied off of either the Phase A or B NSA Project pipelines that would provide the maximum day as well as the peak hour and fire flow supplies for their local areas instead of having to deliver it all from the NSA terminal storage and pumping facility.

During Phase 1, several other pipeline projects would be constructed to deliver water to several areas within the NSA that are likely to experience growth, including the Cordova Hills, Rio del Oro, and Mather South subareas, as well as subareas located in the Sunrise/Douglas region. The locations of the Phase 1 projects in the NSA are shown on Figure 7-8.

Central Service Area

During Phase 1, several pipeline projects would be constructed in the CSA to improve the interconnectedness and looping of the transmission system. No new storage facilities are planned for the CSA in Phase 1. The locations of the Phase 1 projects in the CSA are shown on Figure 7-9.

South Service Area

New groundwater supply facilities will be needed once the max day demand for the SSA reaches the existing groundwater and recycled water capacity. The water supply and storage in the SSA would be increased with the expansion of the Poppy Ridge GWTP (GWTP-1). Several pipeline projects would be constructed to deliver water to the Southeast Policy area and improve interconnectivity. The locations of the Phase 1 projects in the SSA are shown on Figure 7-9.

7.3.1.2 Phase 2 (2026 to 2035)

The water system facilities needed to serve the Phase 2 demands are described for the NSA, CSA, and SSA. The timing for the Phases 2 and 3 pipelines cannot be accurately defined into either Phase 2 or 3 due to the uncertainty about the specific locations and timing of development. Therefore, the pipeline projects for Phases 2 and 3 are not specifically identified by project number.

North Service Area

Additional pipelines would be constructed within the NSA to supply increased demand in the NSA. The locations of the Phase 2 projects in the NSA are shown on Figure 7-10.

Central Service Area

The next water supply facility in the CSA would be the 18 mgd West Jackson GWTP (GWTP-2) that would use the Excelsior well field as its source of groundwater supply. The West Jackson GWTP would be located in the northern part of the CSA. The Excelsior well field would be reactivated to supply the West Jackson GWTP with some additional wells added as part of the GWTP-2 project.

Additional pipelines would be constructed within the CSA to supply increased demand in the CSA. The locations of the Phase 2 projects in the CSA are shown on Figure 7-11.

South Service Area

The Big Horn GWTP Expansion (GWTP-7) would be constructed in the SSA in Phase 2. Additional pipelines would be constructed within the SSA. The locations of the Phase 2 projects in the SSA are shown on Figure 7-11.

7.3.1.3 Phase 3 (2036 to Buildout)

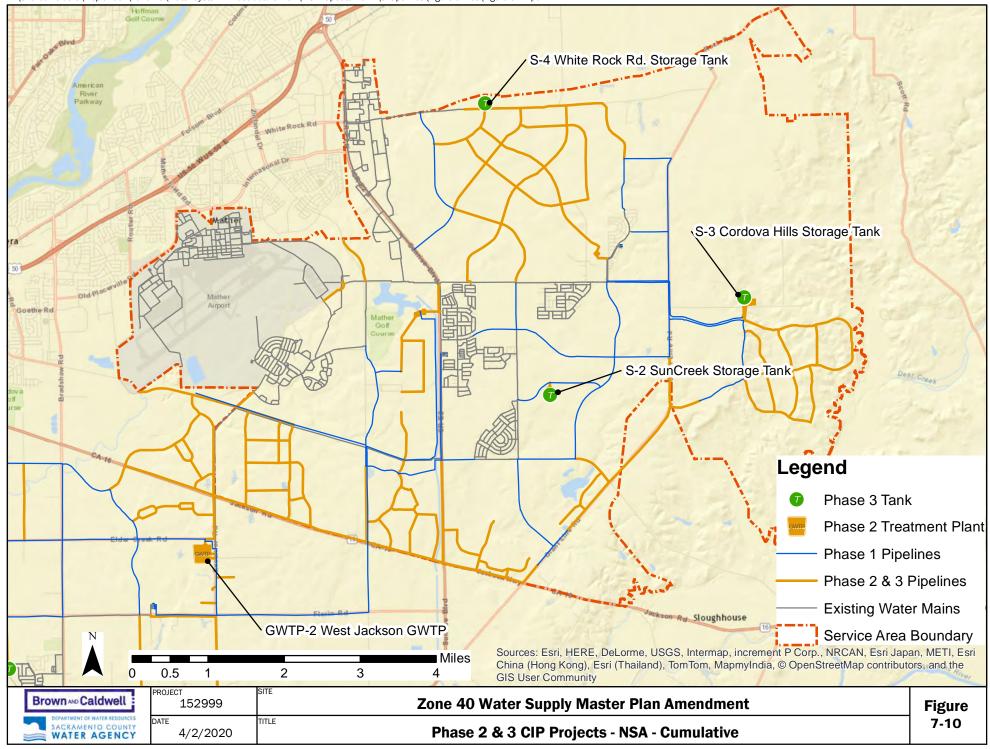

The water system facilities needed to serve Phase 3 demands are described for the NSA, CSA, and SSA.

North Service Area

In Phase 3, the Vineyard WTP would be expanded to 100 mgd from its present capacity of 50 mgd (SW-1). This added surface water supply capacity would be used to supply both the NSA and the CSA, with some supply for the SSA.

Additional storage facilities would be constructed in the NSA in Phase 3 consisting two storage facilities (S-3 and S-4). Additional pipelines would be constructed within the NSA to supply increased demands. The locations of the Phase 3 projects in the NSA are shown on Figure 7-10.

Central Service Area

The surface water supply capacity for the CSA would be increased with the expansion of the Vineyard SWTP (SW-1) from 50 mgd to 100 mgd. The groundwater supply capacity would be increased in the CSA by the construction of one new GWTP and the expansion of one of the existing GWTPs (GWTP 3 and GWTP-4). In addition to the storage that would be constructed at these two GWTPs, one additional storage reservoir would be constructed in the CSA (S-5) and the pump station at a storage facility would be expanded (S-6). Additional pipelines would be constructed within the NSA to supply increased demands.

Facilities would also be added to deliver the POU surface water (19.1 mgd at maximum day) wholesaled by the City (SW-2). In the 2006 WSIP, it was assumed that the POU would be diverted and treated at the City's Fairbairn WTP, and then conveyed to the City's Florin Reservoir through the transmission main in Power Inn Road. The POU water connection to the City would be established at the Florin Reservoir. The water would be pumped out of Florin Reservoir by low-heard pumps; then it would be conveyed in a dedicated transmission main (POU Water Pipeline), and finally the water would fill the North Vineyard Station Storage tank. From there, the water would be pumped out to the CSA.

The delivery of POU water would be significantly impacted by the Hodge flow standard. Recent studies by the City indicated that the POU water for Zone 40 would be subject to cutbacks under certain hydrologic conditions as opposed to being a highly reliable surface water supply as previously thought. Future study and update would be needed once the availability of the POU water is determined.

The locations of the Phase 3 projects in the CSA are shown on Figure 7-11.

South Service Area

The groundwater supply capacity would be increased in the SSA by the construction of two new GWTPs (GWTP-5 and GWTP-6). As shown in Table B-3 in Appendix B, these two GWTPs would provide a total groundwater supply capacity for the SSA that exceeds the SSA's projected maximum day demand at buildout. Consideration should be given to locating these two proposed GWTPs closer to where there is a need for dry year groundwater supply capacity, such as the CSA.

Facilities would also be added to increase the recycled water supply (RW-1). The recycled water project (RW-1) consists of the construction of pipelines, storage, and pumping capacity to deliver recycled water to new customers in the SSA. New storage would consist of the storage provided at the two GWTPs. Additional pipelines would be constructed within the SSA during Phase 3. The locations of the Phase 3 projects in the SSA are shown on Figure 7-11, except for the recycled water project. The specific configuration of the recycled water project has not been defined.

7.3.1.4 **Summary**

The future water system facilities are categorized as supply facilities, storage facilities, and pipelines. Table 7-13 presents the water supply facilities planned for Zone 40. Each GWTP project consists of wells, a groundwater treatment facility, a storage tank, and a pump station that pumps from the storage tank into the distribution system. Some of the GWTP projects already have wells that were previously drilled but not equipped and some would require the equipping and drilling of new wells. Table 7-13 presents the number of wells that would be equipped and/or drilled and equipped for the pertinent GWTP projects.

Table 7-14 presents the storage facility projects planned for Zone 40. Table 7-15 presents the pipeline projects that are 16 inches in diameter or larger planned for Phase 1 for all of Zone 40. Table 7-16 presents the pipelines that would be needed during Phases 2 and 3 for all of Zone 40.

7.3.2 Capital Improvement Plan

This section presents the CIP for Phases 1, 2, and 3.

7.3.2.1 Phase 1 CIP - 10 Year Plan (FY 2020-21 to 2024-25)

The Phase 1 CIP represents the projects that will be constructed over the near term time period and provides the basis for the development of the capacity charge. The development of the Phase 1 CIP requires consideration of the timing and duration of each project. The Phase 1 CIP consists of groundwater, storage, and pipeline projects. No surface water and stand alone storage projects are planned for Phase 1, other than the storage that is part of the GWTP project.

Table 7-17 presents the estimated costs of the Phase 1 water facilities for all of Zone 40. Included in the Phase 1 CIP is an item for non-specific project costs that cover the labor costs of SCWA's planning, development, and development sections.

The timing of the Phase 1 projects presented in Table 7-17 are based on information SCWA has received from developers' engineers regarding the timing of development projects and keeping a somewhat consistent rate of annual expenditure over the duration of Phase 1. The cost of each project would occur over a duration of several years. All of the projects would be completed by the time the end of Phase 1 is reached.

	Table 7-17. Phase 1 CIP Cost Estimate - Baseline									
	Projects			Project	Timing					
No.	Name	Service Area	Capital Cost	Start, FY	End, FY					
Groundwater projects (SC	WA projects)									
GWTP-1	Poppy Ridge GWTP Expansion	SSA	\$13,832,800	2016	2018					
	Well site acquisitions	CSA/SSA	\$180,000	2018	2023

Note: SCWA to verify status of Phase 1 CIP projects.

7.3.2.2 Phase 2 CIP - 10 Year Plan (2026 to 2035)

Phase 2 represents the 10 year period following the end of Phase 1. Since Phase 2 is further in the future, the timing of projects is more speculative and less precise. The level of precision provided in the Phase 1 CIP is not needed for Phase 2 since the capacity charges are developed using the Phase 1 CIP costs and not the CIP costs from the subsequent phases.

The new pipelines that are needed for Zone 40 during Phases 2 and 3 are defined. However, the timing of when each pipeline project is needed is dependent on the location and timing of development. Therefore, this document does not identify the specific pipe segments that would need to be constructed in either Phase 2 or 3. The approach used for the development of the CIP is to assume that approximately half the cost of the Phases 2 and 3 pipelines would occur in Phase 2 and half would occur in Phase 3. Table 7-18 presents the cost estimate for the Phases 2 and 3 pipelines for all of Zone 40.

a. Projects relevant to the three growth areas.

Table 7-19 presents the cost estimate for the Phase 2 CIP projects for all of Zone 40. The Phase 2 CIP consists of groundwater and pipeline projects. No surface water projects are planned for Phase 2.

Table 7-18. Phases 2 and 3 Pipeline Cost Estimate - Baseline						
Diameter, in	Length, ft	Capital Cost				
16	165,716	\$68,859,035				
18	14,351	\$6,751,465				
20	-	\$ -				
24	67,876	\$36,404,178

Total			\$143,454,450				

7.3.2.3 Phase 3 CIP - 17 Year Plan (2036 - Buildout)

The Phase 3 CIP consists of surface water, groundwater, recycled water, storage, and pipeline projects. Table 7-20 presents the cost estimate for the Phase 3 CIP projects for all of Zone 40. The cost estimate for the City POU supply connection (SW-2) is for the construction of the interconnection and the pipeline to convey the water into the CSA's water transmission system. It does not include the City's capacity buy-in cost that was estimated in 2005 to be \$32 million.

Table 7-20. Phase 3 CIP - Baseline						
	Projects					
No.	Name	Service Area	Capital Cost

Pipeline Projects		NSA/CSA/SSA	\$99,778,150			
Total			\$441,059,050			

a. Does not include the City's capacity buy-in cost

7.3.2.4 CIP Summary

Table 7-21 and Figure 7-12 summarize the Zone 40 CIP costs by project category and phase. The Phases A and B NSA projects in Phase 1 have been categorized as storage projects for the purposes of Table 7-21 and Figure 7-12.

Table 7-21. Zone 40 CIP Cost Summary - Baseline								
Project Categories	Phase 1	Phase 2	Phase 3	Total				
Surface Water Projects			\$202,034,400	\$202,034,400				
Groundwater Projects	\$14,012,800	\$43,676,300	\$73,100,600	\$130,789,700				
Recycled Water Projects			\$20,000,000	\$20,000,000				
Storage Projects	\$85,386,140		\$46,145,900	\$131,532,040				
Pipeline Projects	\$102,184,500	\$99,778,150	\$99,778,150	\$301,740,800				
Non-Specific Project Costs	\$30,000,000			\$30,000,000				
Studies	\$1,150,000			\$1,150,000				
Total	\$232,733,440	\$143,454,50	\$441,059,050	\$817,246,940				

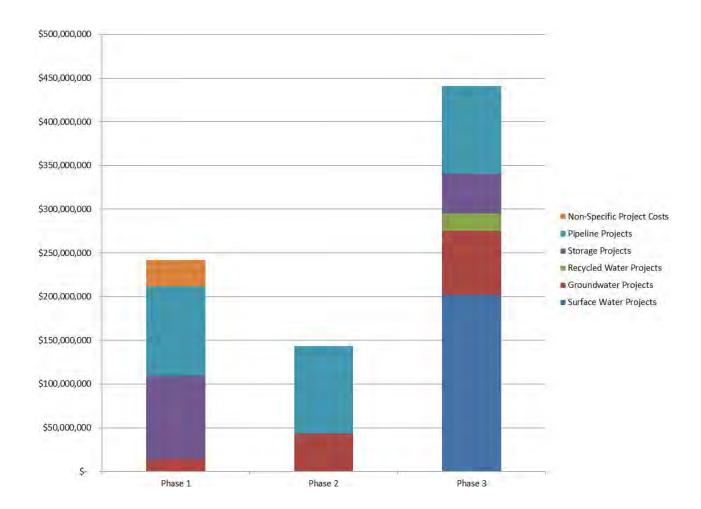

Figure 7-12. CIP summary by phase

Section 8

Multi-Sport Complex and Grant Line Industrial Annexation Area

This section describes the water demands, water supplies, and needed water system improvements for the Plan Area scenario.

8.1 Water Demands

This section describes the land use, demographics, and demand projections for the Plan Area scenario.

8.1.1 Buildout Land Use

This section describes the projected developed area and demographics for the Plan Area and for the overall Plan Area scenario.

8.1.1.1 Plan Area

The source of land use information and water demand projections for the Plan Area is shown below in Table 8-1.

Table 8-1. Source of Land Use Information and Water Demand Projections for the Plan Area					
Subarea Name	Agency Providing Land Use Data and Date				
Plan Area	Wood Rodgers, 12/19/19				

The City of Elk Grove has acquired two parcels totaling approximately 104 acres of property to develop an MSC. The property is located just outside of the southern City of Elk Grove limit and requires annexation into the City of Elk Grove. The City of Elk Grove has initiated the annexation process with LAFCo. One of the LAFCo conditions to annex the 104 acre City of Elk Grove-owned parcels is that adjacent properties also be annexed into the City of Elk Grove's Sphere of Influence. The adjacent properties are located to the west and east of the City of Elk Grove owned parcels, with a total combined area of approximately 572 acres in size (Plan Area). The 572 acre Plan Area, also known as the Elk Grove Multi-Sport Complex and Grant Line Industrial Annexation Area, includes the 104 acre City of Elk Grove owned property.

In general, the project area is located east of Highway 99 and the railroad and south of Grant Line Road. The majority of the existing site is currently being used for agriculture purposes. The existing topography of the project area is flat with elevations varying from 55 feet to 48 feet, and generally falls east to west.

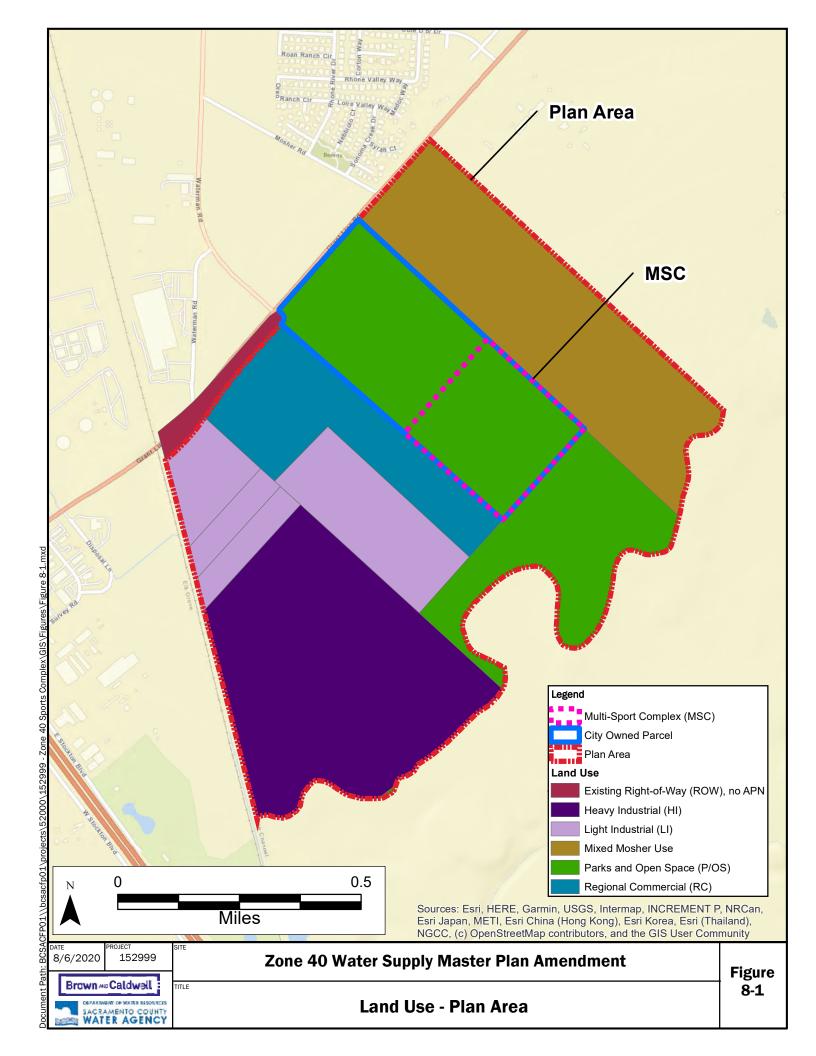

The proposed land uses will consist of mixed use, parks and open space, regional commercial, light industrial, and heavy industrial. Proposed land uses for the Plan Area assumed for this analysis are shown in Table 8-2 (Elk Grove, 2020).

Table 8-2. Land Use Areas for the Plan Area						
Land Use Category Proposed Land Use Area, Acr						
Mixed Mosher Use	118.9					
Parks and Open Space (P/OS)	169.0					
Light Industrial (LI)	112.2					
Regional Commercial (RC)	20.0					
Heavy Industrial (HI)	143.2					
Right-of-Way (ROW)	8.2					
Total	571.5					

Source: Elk Grove, 2020.

8.1.1.2 Plan Area Scenario

The 2010 and buildout developed land use acreages by land use category for Zone 40 with Plan Area are summarized in Table 8-3. The acreages presented in Table 8-3 are net acres for 2010 and gross acres for this scenario at buildout.

Table 8-3. 2010 and Buildout Area by Land Use – Plan Area						
Land Use Category	2010 Developed Area, Net Acres	Buildout Area, Gross Acres				
Rural estate	1,380	6,870				
Single family	6,970	18,140				
Multi-family - low density	220	3,750				
Multi-family - high density	390	1,310				
Commercial	1,520	4,352				
Industrial	1,110	3,729				
Industrial-unutilized	340	575				
Public	920	2,130				
Public recreation	1,270	4,980				
Mixed land use	20	1,350				
Right-of-way	70	580				
Subtotal, municipal water supply land area	14,210	47,770				
Self-supported/supplied by others	-	870				
Non-irrigated	500	9,800				
Agricultural	-	11,620				
Total	14,710	70,060				

Note: Elk Grove wholesale area is not included in the 2010 developed area acreage because it was not available. It is included in the buildout acreage.

As there is no residential land use associated with the Plan Area, the projected DUs and population for the Plan Area scenario are consistent with the Baseline scenario. The number of customer connections for the Plan Area scenario at buildout are currently unknown.

8.1.2 Buildout Water Demands

This section presents the buildout water demand for the Plan Area and for the overall Plan Area scenario. Table 8-4 presents the buildout water demand projection for the Plan Area developed by Wood Rodgers.

Table 8-4. Plan Area Buildout Water Demands ^a							
Land Use	Proposed Land Use Area, Acres	UWDF, ac-ft/yr/ac ^(a)	Water Demand, ac-ft/yr				
Mixed Mosher Use	118.9	2.31	275				
Parks and Open Space (P/OS)	169.0	3.01	509				
Light Industrial (LI)	112.2	2.17	244				
Regional Commercial (RC)	20.0	2.17	43				
Heavy Industrial (HI)	143.2	2.17	311				
Right-of-Way (ROW)	8.2	0.19	2				
Total			1,383				

Source: Elk Grove, 2020.

a. Includes 7.5% system losses.

It is anticipated that the land use plan for the Plan Area will possibly be revised, perhaps several times, before final approval. It is anticipated that these revisions would not significantly change the overall total buildout water demand for Zone 40 from the projections presented in this report, as well as the planned water system improvements. The potential demands of a significant water user (e.g., beverage producer) is not included in the demand projection. Additional analysis would be necessary should a project that includes a significant water user be proposed. If the land use changes and resulting demographics, water demands, and facility needs are determined to be significant, the report would be amended as necessary.

Tables 8-5 present the total buildout Zone 40 water demand for the Plan Area scenario. The recycled water demand in the SSA is included in the demand projections in Table 8-5 to provide the total water demand for this scenario. There is no recycled water demand assumed for the Plan Area. The total Zone 40 demand at buildout for this Plan Area scenario would be 1,400 ac-ft/yr greater than the buildout demand estimated for the Baseline scenario in Table 7-5 of 102,400 ac-ft, or a 1.4 percent increase.

As mentioned in Section 7.1.2, the buildout water demand factors and the total demand for the baseline scenario has not been updated for this amendment. Due to recent reductions in per capita water use, it might be possible that an updated evaluation of the projected Zone 40 demand at buildout may result in a smaller buildout demand for the Baseline and Plan Area scenarios.

Table 8-5. Buildout Water Demand by Land Use Category – Plan Area						
Land Use Category	Water Demand, ac-ft/yr					
Rural estate	9,400					
Single family	38,600					
Multi-family - low density	9,200					
Multi-family - high density	4,400					
Commercial	8,900					
Industrial	7,500					
Public	1,700					
Public recreation	14,000					
Mixed land use	2,900					
Right-of-way	100					
Subtotal (land use with water demand)	96,600					
Water system losses (7.5% of water sales)	7,200					
Self-supplied/supported by others	0					
Industrial-unutilized	0					
Non-irrigated	0					
Agricultural	0					
Total	103,800					

8.1.3 Water Demand Growth Projection

Water demand growth projections are determined assuming the Plan Area will be constructed as early as 2025. The projected water demands by service area are shown in Table 8-6 and illustrated on Figure 8-2.

Table 8-6. Projected Water Demand in 5-Year Increments – Plan Area, ac-ft/yr								
Service Area	2020	2025	2030	2035	2040	2045	2050	Buildout (2052)
NSA	7,300	10,100	13,100	17,500	22,400	27,500	32,800	34,900
CSA								
Plan Area	-	1,400	1,400	1,400	1,400	1,400	1,400	1,400

CSA subtotal	18,400	22,600	25,500	29,500	33,800	38,200	42,700	42,800
SSA	19,700	22,600	25,600	26,100	26,100	26,100	26,100	26,100
Total study area	45,400	55,300	64,200	73,100	82,300	91,800	101,600	103,800

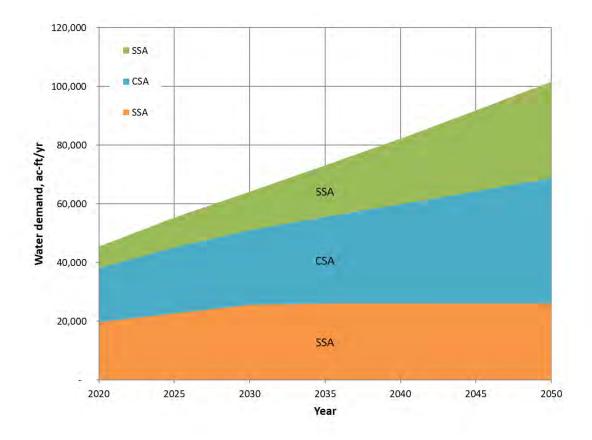

Figure 8-2. Water demand projection - Plan Area

8.2 Water Supply Capacity

This section quantifies the amount of supply capacity that would be needed to meet demands through buildout. The supply capacity and the use of the supply is presented on both a maximum day basis and an annual basis.

8.2.1 Maximum Day Demand Supply Capacity and Use

This section compares the projected maximum day demand to supply capacity for each of the three service areas through buildout. The maximum day demand to supply capacity comparison tables for each of the three service areas are presented in Appendix C. The future supply capacity is based on the proposed supply and conveyance facilities that are presented for the Baseline scenario in Section 7. The maximum day use of each type of supply is quantified for the wet/average years and dry years.

Table 8-11 presents the maximum day demand and supply capacity comparison for Zone 40 from 2020 through buildout. The maximum day use of each type of supply is quantified for the wet/average years and dry years. As can be seen in Table 8-7 and consistent with the established conjunctive use program, the total supply capacity exceeds the maximum day demand for each phase, but neither the groundwater nor surface water supply capacity alone can meet the maximum day demand. The 1.4 percent increase in total Zone 40 demand for the Plan Area scenario compared to the baseline scenario can be supplied with the same supply capacity assumed for the baseline scenario.

As shown in Table 8-7, Zone 40 will utilize a varying mixture of groundwater and surface water supplies on the maximum demand day based on whether it is a wet/average year or a dry year. The observations made for the Baseline scenario in Section 7.2.1.4 pertain to the Plan Area scenario.

Table 8-7. Maximum Day Demand to Supply Comparison for Zone 40 – Plan Area, mgd							
	Pha	se 1	Pha	se 2	Pha	se 3

a. Groundwater supply decrease in 2020 due to Anatolia GWTP removed from service.

Reduction in existing capacity and added future surface water supply capacity in 2020 and 2025 because planned delivery to NSA from existing Vineyard SWTP accounted as future supply capacity as requested by SCWA staff.

8.2.2 Annual Water Supply

Table 8-8 presents the annual supply to demand comparison for a normal climate year. Table 8-9 presents the annual supply to demand comparison for a single dry year and Table 8-10 presents the comparison for a multiple dry year period. The presented supply values are the supplies available to Zone 40 regardless of the capacities of existing supply facilities. The needed facility improvements needed to expand existing supply capacity are presented in Section 8.3. Projections of the use of each supply source that consider supply facility capacity constraints for each service area for normal and dry years are presented in Appendix C.

Table 8-8. Supply and Demand Comparison-Normal Year – Plan Area, ac-ft/yr

Note: The water demand projection and the dry year CVP supply allocation have not been revised for this WSMP amendment.

a. Only 35,000 ac-ft/yr assumed to be available without the construction of seasonal storage, as described in Section 4.2.2.

As can be seen in Tables 8-8, 8-9, and 8-10, as well as in Appendix C, the total water supply capacity is greater than the projected demands. This analysis verifies the sufficiency of the water supply for the Plan Area scenario.

8.2.3 Storage and Pumping Station Capacity Evaluation

Table 8-11 and 8-12 presents a summary comparison of the planned to required storage volume and pumping station capacities for this scenario. As shown in Tables 8-11 and 8-12, the planned storage facilities provide more than the required storage volumes and pump station capacities. No additional storage and/or pump station projects are required to support the Plan Area scenario compared to the Baseline scenario. The detailed storage evaluation tables for each pressure zone are presented in Appendix C.

Table 8-11. Zone 40 Storage Capacity Evaluation Summary – Plan Area						
	Phase 1 (2020-2025)	Phase 2 (2026-2035)	Phase 3 (2036-2052)			
Provided storage volume, MG						
Existing	42.2	42.2	42.2			
Future	13.5	17.5	36.0			
Total	55.7	59.7	78.2			
Required storage volume, MG						
Equalization	19.0	25.5	34.7			
Fire	3.8	3.8	3.8			
Emergency	15.8	21.3	28.9			
Total	38.6	50.6	67.4			
Difference (provided minus required)	17.1	9.1	10.8			

Table 8-12. Zone 40 Pump Station Capacity Evaluation Summary – Plan Area						
	Phase 1 (2020- 2025)	Phase 2 (2026- 2035)	Phase 3 (2036-2052)			
Provided pump station capacity from storage, mgd						
Existing	118.2	112.3	103.4			
Future	20.5	32.6	88.1			
Total	138.7	144.9	191.5			
Required pump station capacity from storage, mgd	96.6	127.9	173.1			
Difference (provided minus required)	42.1	17.0	18.4			

8.3 Water System Facilities and Capital Improvement Program

This section describes the water modeling analysis performed and the water system facilities needed to supply the Plan Area scenario.

8.3.1 Evaluation of System Feasibility to Supply Plan Area

This section evaluates the Zone 40 supply and distribution system infrastructure capacity to convey water to the Plan Area. The Plan Area would be connected to the existing distribution system in the CSA on Grant Line Road as described in the Wood Rogers report (Elk Grove, July 2020).

The maximum day, peak hour, and fire flow demands for the Plan Area will be primarily supplied from the East Elk Grove GWTP and to some extent from the East Park GWTP. Both of these facilities have ground level storage and pump stations. Water is conveyed from these facilities to the Plan Area south down Waterman Road with an existing 24-inch diameter pipeline. This pipeline has a peak hour flow capacity of 14 mgd and a fire flow capacity of 20 mgd. A future 16-inch pipeline is planned for Grant Line Road that will provide additional supply capacity to the Plan Area from a future Bond GWTP that will be located to the north.

Table 8-13 compares the supply capacities from these to two GWTPs to the buildout demands for the two planning subareas in the southern part of the CSA and the Plan Area. As shown in Table 8-13, there is adequate supply capacity to meet the demands of the Plan Area.

Table 8-13. Supply to Demand Comparison, mgd							
	Maximum day	Peak hour	Maximum Day Plus Fire Flow				
Supplies							
East Elk Grove GWTP							
Existing	6.5	13.0	13.0				
Future	6.5	13.0	13.0				
East Park GWTP	2.9	3.5	3.5				
Total	15.9	29.5	29.5				
Demands							
Elk Grove Wholesale	6.0	12.0	12.0				
Grantline 99	0.5	1.0	1.0				
Plan Area	2.5	5.0	8.3				
Total	9.0	18.0	21.3				

SCWA's buildout water model was used to evaluate the water system's ability to supply additional water demands associated with the Plan Area. The buildout water model includes all improvements included in the Baseline scenario as discussed in Section 7.

As the Plan Area is proposed to be located within the CSA, it would be supplied by the SSA-CSA pressure zone. There are two proposed connection points to the existing mains in Grant Line Road.

Water performance was analyzed using a water system model provided by SCWA to ensure the Plan Area can be adequately supplied while meeting design requirements set by the 2016 WSIP. A minimum pressure of 35 psi for distribution mains and 40 psi for transmission mains and a maximum velocity of 7 feet/second (fps) is required under peak hour demand conditions to meet operating goals. A minimum pressure of 20 psi for distribution mains and 25 psi for transmission mains and a maximum velocity of 10 fps is required under maximum day plus fire flow conditions (4,000 gpm).

The following modeling scenarios were prepared and analyzed:

- 1. Phase 1
 - a. Maximum Day Demand
 - b. Peak Hour Demand
 - c. Maximum Day Demand plus Fire flow (4,000 gpm)
- 2. Phase 2
 - a. Maximum Day Demand
 - b. Peak Hour Demand
 - c. Maximum Day Demand plus Fire flow (4,000 gpm)
- 3. Buildout
 - a. Maximum Day Demand
 - b. Peak Hour Demand
 - c. Maximum Day Demand plus Fire flow (4,000 gpm)

Modeling results for these scenarios indicate all operating goals are satisfied. The water system facilities needed to serve the buildout demands are the same as the facilities defined for the Baseline scenario. The expansion of the East Elk Grove GWTP and the extension of the proposed watermain in Grant Line Road are the major CIP projects that impact the Plan Area at buildout. They are both already included in Phase 3 CIP to support the Baseline scenario.

Water modeling results are not included in this report but were presented to SCWA and the City of Elk Grove as a separate technical memorandum.

8.3.2 Capital Improvement Program

The water system improvements defined for the Baseline scenario in Section 7.3 are the same as required for the Plan Area scenario. The exception is that additional water transmission pipelines will be needed to convey water from the interconnections in Grant Line Road to within the Plan Area. A total of 6,645 feet of 16-in transmission main will be required. This Plan Area transmission main will add \$3 million to the total Phase 1 CIP cost presented in Table 7-17 (Elk Grove, 2020).

SACRAMENTO COUNTY WATER AGENCY INTER-OFFICE CORRESPONDENCE Department Of Water Resources

TECHINICAL MEMORANDUM

TO: Kerry Schmitz, Principal Civil Engineer; Darrell Eck, Senior Civil Engineer

FROM: SCWA Staff

DATE: 08/30/2013

SUBJECT: Zone 40 Residential Unit Water Demand Factors

This memo documents an evaluation of current Zone 40 residential unit demand factors based on multiple years of historical water meter data.

BACKGROUND

Water demands based on land use data is the preferred approach in developing water demand projections for existing and new growth areas in Zone 40. Combining land use and historical water demand information links water use and land use to a specific geographic location. This linkage of geography and water demand data becomes more apparent when modeling the water distribution system.

During the Water Forum negotiations (1993 to 2000), Boyle Engineering provided stakeholders with a technical methodology for deriving unit water demand factors based on water use data and county land use data. As a result of this effort a set of unit water demand factors (UWDF) were developed for SCWA and other water purveyors that were based on the Sacramento County regional average water use as described in the "Estimate of Annual Water Demand within Sacramento-Wide Area", (Boyle, May 1995). In this report water demand factors were determined based on 1990 land and water use data rather than actual retail customer data. The report goes on to state:

"To overcome the general incompleteness of the water use information, a methodology was developed wherein the ratio of water demand factors from the 1991 City (of Sacramento) Study was utilized as a basis for apportionment of water use to the specific land use categories in the urban water agencies...the water demand factors were then proportionately scaled up or down to balance the total 1990 water usage with the particular district."

The Water Forum average annual UWDFs were used in determining the unit water demand factors identified in the 2005 Zone 40 Water Supply Master Plan (WSMP), as shown in Table 1. The left column (Land Use Category) identifies the broad land use categories used at the time of the development of the WSMP. The middle column represents the UWDFs for year 2000. The right-hand column represents the UWDFs for Water Forum Buildout – year 2030 which shows reduced unit water demands of 25.6 percent as a result of water conservation measures mandated in the WFA.

Table 1. Zone 40 Unit Water Demand Factors for Year 2000 and Year 2030 in Ac-Ft/Acre

Land UseCategory	2000	2030
Rural Estate	1.57	1.33
Single Family	3.4	2.89
Multi-Family - Low Density	4.36	3.7
Multi-Family - High Density	4.85	4.12
Commercial	3.24	2.75
Industrial	3.19	2.71
Industrial - Unutilized	0	0
Public	1.22	1.04
Public Recreation	4.08	3.46
Mixed Land Use	2.95	2.51
Right-of-Way	0.25	0.21
Vacant	0	0
Agriculture	0	0

HISTORICAL METER DATA

Since the late 90s and early 2000, meters have been installed increasingly on SCWA's existing and new retail customers. Currently, approximately 90% of SCWA's retail customers have active water meters. Meters for the balance of SCWA's retail customers continue to be added/retrofitted, it is projected that nearly all customers will be metered by 2015. For those meters already in use, a large volume of water usage data has been collected for the purpose of billing (for older metered accounts a considerable amount of water usage data is available). For the purposes of this analysis historical meter data was obtained from the County Utilities Billing System (CUBS).

SCWA collects water usage data every two months. Accordingly, annual water use for each customer should be the total of the six readings recorded each year. In addition to water usage data, Assessor's Parcel Number (APN), and the zoning (land use) information are also available as part of the meter data set.

The historical meter data set was then used to evaluate the Zone 40 UWDFs. Specifically,

- 1) to develop UWDFs based on the SCWA's actual water usage data rather than the Sacramento regional average water usage developed more than a decade ago.
- 2) to validate the 2030 UWDFs that assume a 25.6 percent (relative to year 2000) reduction in water demand when implementing the water conservation practices recommendated in the WFA.

The resulting UWDF's from this analysis should provide SCWA staff with information relative to meeting the conservation targets set by the WFA and an ability to decide if changes should be made to the UWDFs represented in the water supply master plan.

METHODOLOGY

The meter data set was processed using Microsoft Access (Access). **Figure 1** shows a sample of the meter database. The first column is "ID", containing the sequence number for each record. The second column is "APN" number associated with each customer. APN number is also a field used to filter out customers that are not inside Zone 40. The third column is "ReadingDate" that shows the reading date for each record. The fourth column is "Reading" that shows the actual meter reading for each record in hundred cubic feet (ccf). The fifth column is "Consumption" that shows the water usage in cubic feet. The last column contains the Zoning information for each customer's property.

Figure 1. Sample of Meter Database

There are over 2 million records in the meter database. The meter data needs to be processed properly to assess the water usage of each land use category in a particular year. This was achieved by creating queries in Access. **Figure 2** shows an example of a query created for water ususage for property zoned RD 7 in 2012. For each meter account the query results shows its APN number, lot size, zoning, and total water usage. Average water usage and lot size are then calculated for all the filtered records. The UWDF is then calculated by diving the average water ususage by the average lot size. Figure 3 provides a screenshot of the above referenced query.

Similarily, the UWDFs for each residential land use catagory were calculated for 2005 through 2012. The UWDFs for non-residential land use were not calculated for this TM.

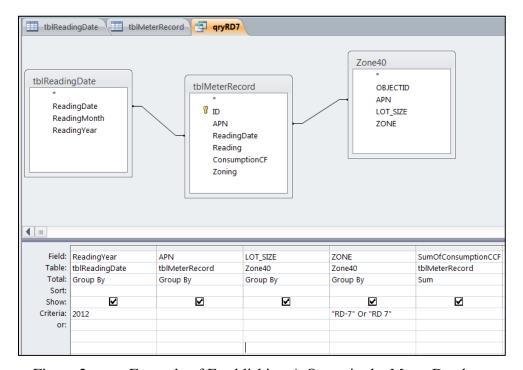

Figure 2. Example of Establishing A Query in the Meter Database

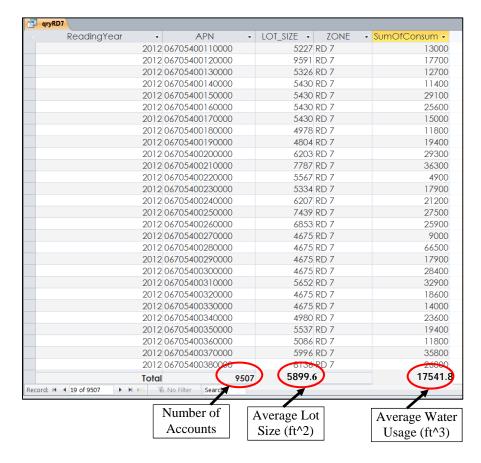

Figure 3. Sample Screenshot of the Query Result for RD 7 in 2012

UNIT WATER DEMAND FACTORS BASED ON METER DATA

The UWDF for each residential land use category for each year are shown in **Table 2** below. **Table 2** indicates that there is a significant variation in UWDFs which generally increase with dwelling density. For example, the UWDF is 1.31 Ac-Ft/Acre for RD 1, 2.66 Ac-Ft/Acre for RD 5, and 3.82 Ac-Ft/Acre for RD 20.

Another observation from **Table 2**, despite the variation certain dwelling density groups have UWDFs that are relatively close in value. Based on this "closeness" four residential categories were identified. They include:

- 1) Very low density residential (VLDR), for RD 1 and RD 2.
- 2) Low density residential (LDR), for RD 3 to RD 5.
- 3) Midium density residential (MDR), for RD 7 to RD 15, and
- 4) High density residential (HDR), for RD 20.

The UWDFs for these four categories are shown in Figures 4 to 7, respectively. Figures 4 to 6 show that for lower density residential categories (MDR and below) the UWDFs increased from 2005 to

2008 and then trended down over the next four years. The trend generally coincides with impacts to the broad national and regional economy, but also could be attributed to the weather, rising water rates, as well as water conservation measures implemented by property owners. For higher density residential (see **Figure 7**) this trend is not repeated. In fact, the UWDF for higher density residential actually increased slightly over the past couple of years.

Table 2. Zone 40 Unit Water Demand Factors Based on Meter Data, Unit: Ac-Ft/Acre

Year	Řesid	v Density lential DR)	Low Density Residential (LDR)			Medium	High Density Residential (HDR)		
	RD 1	RD 2	RD 3	RD 4	RD 5	RD 7	RD 10	RD 15	RD 20

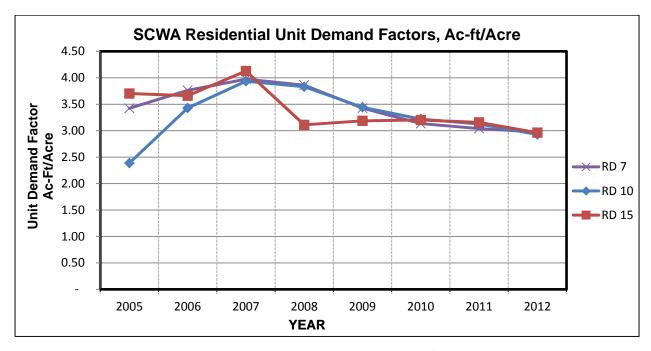

Figure 6. Unit Water Demand Factors for MDR

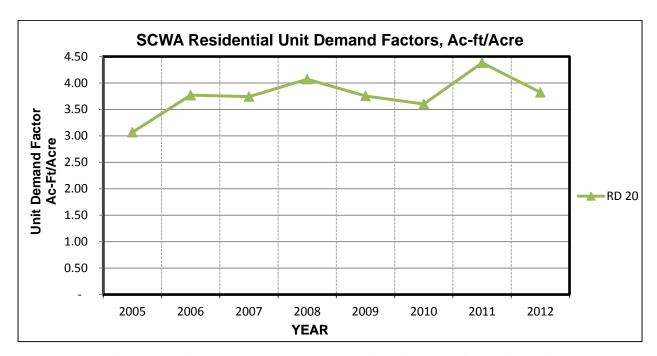

Figure 7. Unit Water Demand Factors for High Density Residential

Table 3 shows the total number of meter accounts for each zoning type from 2005 to 2012. The large majority of meter accounts are associated with RD 4, RD 5, and RD 7 zoning. In 2012, there were 32,930 meter accounts in Zone 40 that were used for this analysis. Of these accounts 0.5% were very low density residential, 64.4% were low density residential, 32.3% were medium density, and 2.7% were high density residential. **Table 4** shows the average lot size in square feet of each residential zoning type.

Table 3. Total Number of Residential Meter Accounts in Zone 40

Year	RD 1	RD 2	RD 3	RD 4	RD 5	RD 7	RD 10	RD 15	RD 20
2005	47	114	179	2,130	13,807	8,120	412	197	684
2006	48	116	200	2,441	15,385	8,853	773	228	737

In water supply planning, water demand estimates are typically performed by applying the UWDF to the acreage of a certain land use category. Most often, the density information (dwelling units per acre) are not specified in a land use map, particularly in the general plan process or early planning stages of a development project. Parcels planned for development are generally identified as "very low density residential", "low density residential", "medium density residential", or "high density residential". This necessitates the development of a composite UWDF to represent each category.

By using the information provided in **Tables 2** to **4**, a weighted average UWDF was developed for each category. Further, a three-year moving average was calculated for these composite UWDFs to take into account various hydrologic conditions and weather (see **Table 5**). An average of the previous three years (as opposed to a longer period) is preferred because it is more representative of the current water use pattern as well as reflective of water conservation measures taken. Therefore, the numbers shown in the last row (highlighted) of **Table 5** are recommended as the current UWDF for each residential category.

Table 5. Three-Year Moving Average Unit Water Demand Factors in Ac-Ft/Acre

Year	Very Low Density Residential (VLDR)	Low Density Residential (LDR)	Midium Density Residential (MDR)	High Density Residential (HDR)
2005				
2006				
2007	2.00	3.15	3.70	3.53
2008	2.10	3.29	3.85	3.86
2009	2.05	3.21	3.75	3.86
2010	1.90	2.98	3.47	3.81
2011	1.72	2.76	3.20	3.91
2012	1.71	2.66	3.05	3.94

NET ACREAGE AND GROSS ACREAGE BASED UNIT WATER DEMAND FACTORS

Net acreage is defined as the acreage of all residential lots in a subdivision excluding minor streets. Gross acreage is defined as the total acreage of a subdivision including all residential lots and minor streets. Typically, approximately 20% of the land is dedicated to minor streets in a subdivision.

To calculate projected water demand for a subdivision, the UWDF corresponding to the planned land use category is multiplied by the acreage of a subdivision. If net acreage is used, then a net acreage based UWDF should be applied. Similarily, if the gross acreage is used then a gross acreage based UWDF should be applied.

The UWDFs developed from meter data and shown in **Table 5** are net acreage based. To convert to gross net acreage based value, the net acreage based UWDF should be reduced by 20% to take into account acreage for minor streets. **Table 6** shows the net acreage and gross acreage based UWDFs.

Table 6. Net Acreage and Gross Acreage Based Water Demand Factors in Ac-Ft/Acre

Land Use Category	Net Acreage Based	Gross Acreage Based
Very Low Density Residential (VLDR)	1.71	1.37
Low Density Residential (LDR)	2.66	2.13
Midium Density Residential (MDR)	3.05	2.44
High Density Residential (HDR)	3.94	3.15

COMPARISION TO WSMP

As mentioned earlier, the UWDF in the WSMP for build-out was developed based on a combination of regional water and land use data and an assumption of a 25.6% demand reduction as a result of conservation measures mandated by the WFA. By using extensive historical meter data, the UWDFs developed in this TM should give staff a higher level of confidence when evaluating future water demands and water supply reliablity. **Table 7** shows how UWDFs developed based on meter data in this TM compared to those in the current WSMP. It should be noted that the UWDFs in the WSMP are gross acreage based values.

As shown in **Table 7**, the UWDFs developed in this TM are lower than those in the WSMP, with the exception of the "very low density residential" category, which is only slightly higher. The UWDF of 2.89 Ac-Ft/Acre for "Single Family Residential" in the WSMP (corresponding ot "Low Density").

Residential") is now 2.13 Ac-Ft/Acre based on meter data. The value for "Multi-Family Low Density" (corresponding to "Medium Density Residential") is 3.70 Ac-Ft/Acre in the WSMP as opposed to 2.44 Ac-Ft/Acre based on meter data. For "Multi-Family High Density" (corresponding to "High Density Residential") the value is 4.12 Ac-Ft/Acre in the WSMP compared to 3.15 Ac-ft/Acre based on meter data.

Table 7. Comparison of Unit Water Demand Factors between WSMP and This TM, in Ac-Ft/Acre

Land Use Category in WSMP	Land Use Category in This TM	2030 Unit Water Demand Factor in WSMP	Unit Water Demand Factor Based on Meter Data (Gross Acreage Based)
Rural Estate	Very Low Density Residential (VLDR)	1.33	1.37
Single Family	Low Density Residential (LDR)	2.89	2.13
Multi-Family - Low Density	Midium Density Residential (MDR)	3.70	2.44
Multi-Family - High Density	High Density Residential (HDR)	4.12	3.15

RECOMMENDATIONS

SCWA's meter database provides a extensive historical water use record of its customers. Using a sound statistical approach, along with the land use information in the meter database, a UWDF was developed for each residential density category. This process when compared to the approach taken in the 2005 WSMP has the following advantages:

- The meter data is unique to Zone 40
- The meter data covers a long period of time
- The UWDFs for buildout in the WSMP are projected or targeted numbers assuming a reduction of 25.6% of water use (relative to year 2000) due to improved conservation practices. The UWDFs based on meter data are not projected or targeted numbers instead, they represent the actual historical water use.

The resulting UWDFs indicate that those referenced in the WSMP were overestimated. It also indicates that SCWA has been moving in the right direction with regard to water conservation and demand management. It is recommended that the results documented in this TM should be considered for incorporation in future water supply master plan updates and other water planning documents.

For non-residential/commercial customers, the UWDFs have not been evaluated based on meter data in this TM, primarily due to low number of meter accounts and a greater variation in water use

because of significant differences in commercial activities. It is recommended that the UWDFs currently described in the WSMP continue to be used for non-residential/commercial applications until more data becomes available.
